San Insp. J. H. ERVIN, proceed to Newport News, Va., for duty in connection with extracantonment sanitation.

Medical News

(Physicians will confer a favor by sending for this department items of news of more or less general interest; such as relate to society activities, new hospitals, education, public health, etc.)

CALIFORNIA

School Taken Over as Hospital.—Naval Officers at Mare Island arranged, January 13, to take over St. Vincent's Catholic School, Vallejo, and operate a hospital for influenza patients in these buildings.

Board of Health Resigns.—The board of health of Fresno resigned, January 3, following the failure of the city council to pass an ordinance providing for the complete closing of all places of amusement, churches and saloons as a measure to check the spread of influenza.

Work Against Tuberculosis.—The attitude of the public toward tuberculosis has changed materially since 1914, when an appropriation of $150,000 for the construction of sanatoriums failed to pass legislature. At present counties have provided special hospitals at the cost of $1,646,000 for the work against tuberculosis, and there are now fifteen subsidized hospitals either in operation or in process of construction.

Personal.—Dr. Thurlow S. Miller, San Francisco, was struck by an automobile while crossing a street, January 2, and sustained painful injuries.——Dr. Henry C. Bush, Colfax, has been appointed superintendent of the Arroyo Sanatorium, Tuberculosis Hospital of Alameda County at Livermore, to succeed Dr. Guy F. Rogers, who has resigned.——Dr. J. Severy Hibben has been appointed health officer and city physician of Pasadena, to succeed Dr. Stanley P. Black.

Medical Lectures.—Stanford University Medical School has commenced its thirty-seventh course of popular medical lectures to be held in Lane Hall, every Friday evening. The chief subject of the lectures is "Lessons of the Great War." The special subjects are: "The Rehabilitation and Reeducation of the Wounded and Injured," Mr. A. J. Pillsbury, Sr.; "What the War Has Taught Us in Regard to the Food Supply of the People," Prof. M. Jaffa; "What the War Has Taught Us in Regard to the Control of Venereal Diseases," Dr. Lewis Michelson; "What the War Has Taught Us in Regard to the Physical Condition of Our Young Men," Dr. Philip Hale Pierson; "The Children's Year; a Reconstruction Program," Dr. Adelaide Brown, and "The Control of Epidemics," Dr. William C. Hassler.

ILLINOIS

Personal.—Dr. Fred M. F. Meixner has been appointed commissioner of health of Peoria, to succeed Dr. George Parker, who has resigned.——Dr. Walter Wilhelmj has been elected chairman of the social hygiene clinic of East St. Louis.

Gastro-Enteritis Outbreak.—January 5, the commissioner of health of Peoria reported a fresh outbreak of gastroenteritis presumably due to water infection. The board of health assisted by the state department of health is endeavoring to locate the source of infection. There are from 2,000 to 3,000 cases reported in the city.

New Officers.—At the annual meeting of the St. Clair County Medical Society, held at Belleville, January 9, Dr. Walter Wilhemj, East St. Louis, was elected president; Dr. John C. Gunn, Belleville, vice president; Dr. Charles W. Lillie, East St. Louis, secretary, and Dr. Adolph E. Hansing, Belleville, was reappointed treasurer for the twentieth consecutive term.

Chicago

Honor for Occupational Therapist.—Mrs. Eleanor Slagle of the Henry Favill School of Occupational Therapy, has been appointed supervisor of aids in occupational therapy in the Medical Department of the United States Army.

Personal.—Albert E. Halstead, lieutenant-colonel, M. C., U. S. Army, is on his way home from France.——Franklin H. Martin, colonel, M. C., U. S. Army, who went abroad, November 9, reached New York, January 16, ill with bronchitis.——Leonard S. Wood, major-general, M. C., U. S. Army, has assumed command of the central department, succeeding Thomas H. Barry, major-general, U. S. Army.——Julius H. Hess, major, M. C., U. S. Army, received his discharge, December 25, as chief of the medical service of General Hospital No. 25, Fort Benjamin Harrison, Ind.

MARYLAND

Meetings.—A meeting arranged under the joint auspices of the Baltimore City Medical Society and the Red Cross Institute for the Blind was held at Osler Hall, in the Medical and Chirurgical Faculty Building, Baltimore, January 17, when Sir Arthur Pearson, the founder and director of St. Dunstan's Hostel, London, spoke on "What Is Being Done for Soldiers and Sailors Blinded in the World War at St. Dunstan's." Lieut.-Col. James Bordley, Baltimore, director of America's work for blinded soldiers, sailors and marines, told what was being done at Evergreen (U. S. Army General Hospital No. 7) and at the Red Cross Institute for the Blind in Baltimore.

Personal.—Col. Hugh Hampton Young, Major Louis C. Lehr, Washington, D. C., and Major William A. Fisher, Baltimore, are scheduled to arrive at New York aboard the *Caronia*, January 26.——Dr. Arthur Woo, chairman of the Chinese Christian Movement in Great Britain, who is at present studying at the Johns Hopkins Hospital and Medical School, gave an address at Brown Memorial Church, Baltimore. Dr. Woo was brought to this country by the Rockefeller Foundation for the purpose of studying American medical and hospital methods. Later he will visit the Mayo Clinic and finally head the medical staff at the Union Medical College at Pekin, China.——Dr. Francis X. Kearney, Baltimore, has been made superintendent of Mercy Hospital, to succeed Dr. Edward P. Smith, who resigned to enter military service.

Influenza Increasing.—More than 18,000 cases of influenza have been reported to the state board of health since January 1, but comparatively few fatalities have resulted. Because of new cases in Anne Arundel County, a number of schools in the rural section have been closed by the superintendent of education until conditions show improvement. In Montgomery County the chairman of the Red Cross chapter has asked the various Red Cross organizations to devote themselves to relieving the distress caused by the epidemic now prevailing. The idea is that each organization name a committee to take charge of the work in its locality and use funds it has available. Assistance has been sent on request to Somerset County, lower Dorchester County and Frederick County where the disease has been most prevalent, so far as the state is concerned. Two hundred and fifty-one cases were reported for Baltimore and 275 in the counties recently during a twenty-four hour period. The situation in the city was discussed at a conference Health Commissioner Blake had with the heads of the divisions constituting his department. It was shown that no section of town is free from the disease, but it is of a much milder type than heretofore. Since the beginning of the epidemic last September, 66,350 cases have been recorded at the office of the state board of health, and 22,752 at the local department, or approximately 90,000 for the city and counties.

MAINE

Tuberculosis Drive Opens.—January 6, the first day of the drive for membership campaign of the Androscoggin Anti-Tuberculosis Association, Lewiston, $5,000 was received.

Society Meeting.—At the ninety-fifth quarterly meeting of the York County Medical Society, held in Biddeford, January 2, Dr. Ansel S. Davis, Springvale, was elected president; Dr. Frank W. Smith, York Village, vice president; Dr. A. Leon Jones, Old Orchard, secretary, and Dr. Charles F. Traynor, Biddeford, treasurer.

Committee on Cancer Control.—Dr. Leverett D. Bristol, Augusta, state commissioner of health and chairman of the Maine committee for the control of cancer, has named the following physicians as members of the committee: Alfred D. Sawyer, Fort Fairfield; Donald B. Cragin, Waterville; Eugene B. Sanger, Bangor; Wallace E. Webber, Lewiston; George H. Coombs, Waldoboro; Walter E. Tobie, Portland, and Walter N. Miner, Calais. Through the chairmanship of Health Commissioner Bristol the cancer control work of the committee will be directly identified with the state health department.

MICHIGAN

State Health Association Organized.—Health officers of the state met in Lansing, January 7, and organized the Michigan Health Association, and elected Dr. Alvin H. Rockwell, Kalamazoo, president; C. Parnell, Ann Arbor, vice president, and Dr. William DeKleine, Flint, secretary.

New Health Magazine.—The first number of *Michigan Out-of-Doors* has just been issued by the Michigan Anti-Tuberculosis Association, taking the place of the bulletin of the association. It is published in the interests of the anti-tuberculosis campaign in the state.

Health Budget.—The tentative budget of the department of health for the year totals $2,480,000. This includes the sums needed for additions to a number of contagious disease units, rearrangements and changes in buildings of the Herman Keifer Group, new units required for treatment of pneumonia and venereal disease, $200,000 for extension of the hospital power plant, and the instalment of a new and better hospital laundry and administration offices, $150,000 for a smallpox hospital, $300,000 for a new maternity hospital, and $5,000 for a new department of health building.

Personal.—Dr. Albert T. Getchell, Mount Pleasant, was seriously injured in a collision between automobiles, January 5.——Dr. Garner M. Byington, Charlotte, has been placed in charge of the social disease section of the state board of health service.——Capt. Henry F. Vaughan, S. C., U. S. Army, has been recalled from military service, presumably to succeed Dr. James W. Inches as health commissioner of Detroit. Dr. Inches became police surgeon of the city, January 15.——Dr. Stephen C. Mason has been appointed health officer of Menominee, to succeed Dr. Robert G. Marriner, deceased.

MINNESOTA

Honor Veteran Members.—At the annual meeting of the Southern Minnesota Medical Association, held in Mankato, January 20, the exercises of the session were inaugurated by an honorary recognition by the association of two of its veteran members, Drs. John H. James, Mankato, and George F. Merritt, St. Peter.

Personal.—Dr. W. B. Wright, assistant superintendent of the St. Paul City and County Hospital, resigned, January 9. ——At the annual meeting of the Clay-Becker Tuberculosis Commission, held at Sand Beach Sanatorium, near Lake Park, January 9, Dr. Olaf J. Hagan, Moorhead, was reelected president, and Dr. Oesten K. Windberg, Lake Park, vice president.——Dr. Ignatius J. Murphy, St. Paul, for three years executive secretary of the Minnesota Public Health Association, has resigned to take up postgraduate work in Boston.——Dr. Ernest E. Wells, Stillwater, has succeeded Dr. Charles Van Cappellen, Stillwater, as county physician and poor commissioner of Washington County.

NEW JERSEY

Health Department Activities in Newark in 1918.—According to the monthly bulletin of the department of health of Newark the new activities of the department during 1918 included the establishment of a bureau of venereal diseases, a drug addict clinic in the city dispensary, extension of the free dental clinic in the dispensary, a school of instruction for department employees, supervision of cattle slaughtering by department veterinarians, a clean-up campaign, the registration of midwives, the muzzling of dogs and the control of a typhoid fever outbreak at the Boys' Home at Verona.

NEW YORK

Election.—At the annual meeting of the Canandaigua Society for Physicians and Surgeons, January 9, Dr. William A. Bing was elected president, Dr. Harry M. Smith, vice president, and Dr. George W. Gregg, secretary-treasurer.

Dr. Bernstein Exonerated.—The committee appointed by the state board of charities to investigate a complaint made by the Utica Trades Association on conditions said to exist in the Rome State Custodial Asylum has reported that "As no testimony to substantiate the general or specific charge of the complaint has been made, the committee is of the unanimous opinion that the charges are not sustained and Dr. Charles Bernstein of the Rome State Custodial Asylum has been completely exonerated."

Governor Would Abolish Drug Control Board.—Governor Smith has asked the legislature to immediately abolish the State Narcotic Drug Control Commission as an unnecessary bureau entailing unnecessary expense to the state. In a special message to the law makers the governor suggests that the work of the commission should be taken over by a bureau to be created in the state department of health. Governor Smith expresses himself as in sympathy with the purposes of the antinarcotic drug law and believes that the state should provide for the regulation and control of the sale of narcotic drugs.

School Diet Kitchens in the Influenza Epidemic.—In Syracuse, at the instigation of Dr. Frederick W. Sears, state sanitary supervisor of the district, the diet kitchens of many of the schools, which were not then in operation, were made use of to cook meals for families totally disabled during the recent influenza epidemic. The food was distributed by automobile. The work was financed by the Red Cross and was carried out through the cooperation of the supervisor, the Red Cross, the superintendent of the schools and the director of school diet kitchens. A total of 16,982 meals were served during the first week at a cost of $847.82, a per capita cost of only 4 cents. Later as the patients began to need more substantial food the cost increased.

Personal.—Dr. Francis E. Fronczak, major, M. C., U. S. Army, and formerly health commisioner of Buffalo, is expected to be temporary representative of Poland at the first peace conference at Versailles, January 18, pending the arrival of the Polish delegate proper.——Dr. Harry C. Hummell, Rochester, for several years health officer of Irondequoit, has resigned. The town board of Irondequoit gave a dinner, January 9, in his honor and presented him with a silver loving cup.——Dr. Paul D. Taddiken, Ogdensburg, has been appointed medical superintendent for the Buffalo State Hospital for the Insane, to succeed Dr. George W. Gorrill, deceased. Dr. Taddiken's place as superintendent of the St. Lawrence State Hospital has been filled by the returning of Dr. Richard H. Hutchings, Ogdensburg, who was superintendent until he resigned to enter the military service.——Dr. Frank Crowther, Schenectady, has been elected a member of the Congress in the Thirtieth Congressional District.——Dr. Walter B. Jennings, Norwich, has been offered a position in the State Hospital, Trenton, N. J.

Drastic Prohibition Bill.—A bill enforcing prohibition in New York state in ratification of the federal amendment has been prepared for introduction into the legislature. Very stringent regulations are laid down in connection with the sale of alcohol and wine by druggists. No sales will be made for medicinal purposes except on a physician's prescription and an affidavit would be required of all persons purchasing for mechanical, chemical or sacramental purposes.

A pharmacist's license to sell alcohol would be issued only to druggists who have never been convicted of illegal sale of liquor, whose stock of alcohol shall not represent more than 1 per cent. of the value of all the goods in his place of business and who himself is not addicted to the use of alcohol or drugs. The sale of toilet, culinary, medicinal, antiseptic and flavoring extracts and patent medicines, the manufacture of which requires the payment of a United States liquor dealer's tax would be prohibited. No one but a licensed druggist would be permitted to sell certain compounds and patent medicines named in the bill except on the prescription of a licensed physician. Physicians would be required to keep a record of all prescriptions issued by them for alcoholic compounds and the medical practitioners allowed to issue such prescriptions would first have to give bond of $2,000 for observing the provisions of the law and be licensed by the prohibition commissioner.

New York City

Personal.—Dr. Harold M. Hayes has returned from active service in France and has resumed his practice in this city.——Dr. Frederick W. Splint has been appointed superintendent of the Binghamton City Hospital.——Dr. Bruno S. Horowicz has been appointed assistant sanitary superintendent in the department of health.

United Hospital Fund.—At the annual meeting of the United Hospital Fund, which collects funds for distribution among forty hospitals of the city which give free treatment to the poor, the treasurer announced that the receipts for the fiscal year just ended were $183,778, a gain of 36 per cent. over the previous year. Attention is called to the fact that war conditions as well as the influenza epidemic have seriously increased the demands made on the hospitals, and that in order to meet these demands it will be necessary to raise $250,000 during the present year. Of 151,655 patients treated in the united hospitals last year 48 per cent. did not pay a cent.; 30 per cent. paid in part, and 22 per cent. were private patients. Dr. George E. Brewer, W. V. S., Thorne and James McVickar Breed were elected trustees of the fund.

Accuse Mayor of Bringing Politics Into Health Department.—The Central Federated Union accused Mayor Hylan of renewing his attempt to throw the department of health into politics. At a recent meeting of this organization resolutions were adopted protesting to Health Commissioner Dr. Royal S. Copeland against what was termed his "secret and surreptitious" removal of the division of industrial hygiene, of which Dr. Louis I. Harris was the director, from the bureau of preventable diseases, to his own office. The federated union in the resolutions adopted complains against the disturbance of the work of the division of industrial hygiene, "as constituting a danger, not only to workers, but to the community as a whole," and asks that a committee of five be appointed to take such action as may be necessary, jointly with other central bodies, to exert every effort to prevent this unfavorable interference with an official who has won the confidence and respect of all those interested in health protection of the public. Dr. Copeland declares that no powers will be taken from Dr. Harris, but that Dr. Harris's work has been very onerous aside from the work of the division of industrial hygiene and that he considered the work of this division so important that he wished to have it directly under his supervision. He asserts that Mayor Hylan has had nothing to do with the change. In reply to the complaint of the federated union that its representatives were not consulted by the health commissioner in making the change, Dr. Copeland states that there is no reason why he should consult with them as the work he has in view is work that has not been done before. He is planning to go into industrial establishments, examine the heating, lighting and ventilation, see that sanitary arrangements are satisfactory and investigate the conditions in the handling of food.

OHIO

Influenza at the Orphanage.—Every one of the 156 boys and girls at the orphanage at Fairmount had influenza during the epidemic, but all recovered. There has not been a death in the home from any cause for two and a half years. The institution was closed for three months to visitors during the epidemic.

Governor Recommends Health Organization Changes.—Governor Cox, in his recent inaugural address, recommended that the state be divided into sanitary districts with experienced full-time men in charge of the districts. The governor believed that with this arrangement it would have been easier to manage the epidemic of influenza. In this Dr. William H. Peters, health officer of Cincinnati, agrees. At present there are about 2,200 health officials in the state, many of whom are not physicians and know nothing of sanitation.

OKLAHOMA

Personal.—Dr. Fred S. Clinton, Tulsa, was elected a director of the Oklahoma State Historical Society at its meeting in Oklahoma City, January 14.

Hospital for Negroes.—Possession of the Williams Building, Tulsa, which is to be used as a hospital for colored people, was obtained, January 14, and the institution will be opened this week to receive patients.

New Officers.—At the annual meeting of the Grady County Medical Association, held at Chickasha, December 11, Dr. Martha J. Bledsoe was elected president; Dr. Udonna C. Boon, vice president; Dr. Joe C. Ambrister, secretary-treasurer, all of Chickasha.

Antituberculosis Society Needs Aid.—The Tulsa Anti-Tuberculosis Society is already handling forty-three cases of tuberculosis and its estimated expenses for the current year are not less than $13,000. It is, therefore, making plans to ask the state legislature for an appropriation of not less than $10,000 to help in the local situation in addition to financing the proposed sanatoriums to be built by the state.

SOUTH CAROLINA

Ward for Negroes at State Sanatorium.—The state board of health has decided to ask the legislature for a ward for negroes to be erected on the grounds of the South Carolina Sanatorium, Columbia. The sanatorium is under the charge of Dr. Ernest Cooper, Columbia, as resident superintendent, and the resident physician is Dr. Wilfred R. Claytor.

SOUTH DAKOTA

Smallpox at Huron.—Dr. Charles H. Hall, vice president of the board of health, announces that there are six persons in Huron ill with smallpox. All the cases are under quarantine and are mild in degree.

New Officers.—At the annual meeting of the Sioux Falls District Medical Society, held in Sioux Falls, January 7, Dr. John B. Eagan, Dell Rapids, was elected president; Dr. William E. Donahoe, Sioux Falls, vice president, and Dr. Samuel A. Keller, Sioux Falls, secretary-treasurer.

Personal.—Dr. Henry B. Noble, Howard, has retired from practice.——Dr. Andreas A. Wipf, Freeman, formerly a member of the state legislature and a practitioner for twenty-five years, has retired on account of ill health.——Dr. Louis Holtz has resigned as city health officer of Aberdeen and will devote his attention to private practice and to laboratory work.

PENNSYLVANIA

Personal.—Dr. Arthur M. Calvert, formerly of the Cincinnati Tuberculosis Sanatorium, was made superintendent of the Grand View Sanatorium, Oil City, Pa., January 1.——Dr. Clarence R. Phillips has been elected chairman of the mental clinic, Harrisburg, and the following physicians were elected members of the board of directors: Drs. Norman B. Shepler and Clarence R. Phillips.

New Officers.—The Physicians' Protective Association of Easton held its annual meeting, January 7, and elected the following officers: president, Dr. Oscar M. Richards; vice presidents, Drs. Rueben S. Raub and Joseph S. Cohen, and secretary-treasurer, Dr. W. Gilbert Tillman.——York County Medical Society at its annual meeting, January 2, elected the following officers: president, Dr. John Gilbert, York; vice presidents, Drs. G. Elmer Krout, Jacobus, and Gladfelter E. Spotz, York; secretary, Dr. Nathan C. Wallace, Dover, and treasurer, Dr. Charles W. Eisenhower, York.

Philadelphia

Personal—John Dean Elliotf, major, M. C., U. S. Army, is on his way home after nearly a year of overseas service.——Drs. Otto P. Borger and Samuel L. Immerman have been made assistant school medical inspectors by the director of the health department.

Hospital Lease Ready.—The lease of two wings of the Philadelphia General Hospital to the government for the care and treatment of wounded and sick soldiers, which was authorized by an ordinance that passed councils, January 17, was forwarded to Washington to receive the signature of Secretary Baker. The rental consideration is $1 a year

Medical Club Election.—The Medical Club of Philadelphia at its annual business meeting held at the Bellevue-Stratford, January 17, elected the following officers: Dr. G. Oram Ring, president; Drs. Barton Cooke Hirst and Henry Beates, vice presidents; Dr. William S. Wray, secretary; Dr. Lewis H. Adler, Jr., treasurer, and Dr. Edward E. Montgomery, governor.

TENNESSEE

Personal.—Dr. Newton F. Raines, Raines, was seriously injured in a collision between his automobile and an Illinois Central train, while driving over a grade crossing near his home.——Dr. Max J. Sterne, head of the health and sanitary department of Harriman, has resigned and has been succeeded by Dr. Joseph M. Ellenberger.

State Health Board Held Supreme.—By the provisions of an opinion rendered, December 23, to Dr. Olin West, executive officer of the state board of health, by State Attorney Frank M. Thompson the authority of the state board of health over the county and municipal health boards in the suppression of communicable diseases is supreme.

Hospital Items.—A building for tuberculosis patients is much needed at the Eastern Hospital for the Insane, Knoxville.——The Baird-Dulaney Hospital, Dyersburg, is planning extensive improvements, including the establishment of a school for nurses.——The new hospital at the Davidson County Jail was opened, December 14. The hospital will accommodate twelve patients and is thoroughly equipped.——Fire at the Lincoln Memorial Hospital, December 3, damaged a hospital ward of about fifteen beds and caused a loss of from $5,000 to $8,000. Fourteen patients in private rooms and two small wards were removed to the Knoxville General Hospital without casualty.——A new hospital is to be opened at Nashville by Dr. Rufus E. Fort and other local physicians on the site of the Nashville College for Young Women. The hospital will be operated on a 125 bed basis.

TEXAS

Meeting Postponed.—The semiannual meeting of the Northern Texas Medical Association, which was to have been held in Dallas in December, has been postponed for six months.

Personal.—Dr. Edwin C. Ferguson has resigned as health officer of Beaumont, his resignation to become effective, January 21.——Dr. William M. Trimble, Fort Worth, has been reappointed physician for Tarrant County.

Deficiency Appropriation for State Tuberculosis Colony.—As the result of a conference between the governor and Dr. Joseph B. McKnight, superintendent of the State Tuberculosis Colony, Carlsbad, December 23, a deficiency allowance of $20,000 was granted to complete two new dormitories of eighty beds at the institution. There is already a waiting list which will fill the dormitories as soon as they are completed.

New Officers.—At the annual meeting of the Dallas County Medical Society, December 26, Dr. David L. Bettison, Dallas, was elected president and Dr. Minnie L. Maffet and William W. Fowler, both of Dallas, were reelected vice president and secretary-treasurer, respectively.——At the annual meeting of the Tarrant County Medical Society, held in Fort Worth, December 20, Dr. John H. McLean was elected president; Dr. Edwin P. Hall, vice president; Dr. Robert W. Moore secretary, and Dr. Samuel A. Woodward, treasurer.

Health Commission Meet.—The first meeting of the recently created State Commission on Public Health was held in Dallas, December 5. The organizations represented are: the State Medical Association of Texas, State Council of State Medical Association of Texas, State Council of Defense, Committee on Sanitation and Medicine, Texas Town and City Planning Association, State Social Hygiene Association, Public Schools of Texas, Texas Public Health Association, League of Texas Municipalities, State Board of Health, International Health Board, United States Public Health Service and University of Texas, Extension Department.

GENERAL

National Health Tournament.—A "National Tournament in Health Knighthood" will be conducted for the schoolchildren of America, beginning Feb. 9, 1919. The tournament will cover fifteen consecutive weeks of the school year among classes of ungraded schools and the contest will be for credits on a "Record of Health Chores" according to the rules and conditions established, information concerning which may be had from the state antituberculosis associations or health associations of each state.

Personal.—Col. William N. Bispham, M. C., U. S. Army, is announced as the new commanding officer of U. S. General Hospital No. 28, Fort Sheridan, Ill., succeeding Dr. Theodore S. Proxmire, Lake Forest, resigned.——Brig.-Gen. Francis A. Winter, M. C., U. S. Army, has been assigned as commandant of the Army Medical School, Washington, D. C., relieving Col. Weston P. Chamberlain, M. C., U. S. Army, who has been assigned to duty in the office of the Surgeon-General.——Surg. George M. Converse, U. S. P. H. S., San Francisco, who has been in charge of the Portsmouth-Norfolk (Va.) County Health District, has sailed on a special mission to France.

New Publications on Cancer.—A new pamphlet on cancer for distribution to the medical profession has been prepared by a special committee appointed by the board of directors of the American Control of Cancer. The committee includes Drs. Robert B. Greenough, Boston, chairman; James Ewing, New York City, and Jonathan M. Wainwright, Scranton, Pa. The pamphlet will be published in cooperation with the American Medical Association, and is now in press. A new edition of the American Red Cross textbook on "Home Hygiene and Care of the Sick" has been issued. This book contains a chapter dealing with cancer, enumerating early signs of cancer and precursors of cancer, together with a warning to have such conditions given early and competent attention.

Bequests and Donations.—The following bequests and donations have recently been announced:

Jewish Hospital, Philadelphia, and United Hebrew Charities each $2,500 by the will of Walter A. Kuhn.

Germantown and Chestnut Hill Hospital, Philadelphia, each $1,000 by the will of Sarah R. Watson.

St. Vincent's Home, Philadelphia, and Maternity Hospital, each $11,000, and Philadelphia Home for Incurables, $4,000 by the will of Annie E. Sinnott.

Mt. Sinai Hospital and Mt. Sinai Training School for Nurses, New York City, each $10,000 by the will of Kalman Haas.

Columbus, Ohio, Society for the Prevention and Cure of Tuberculosis for a Children's Preventorium, $3,000 by Mrs. William G. Deshler, conditional on an equal amount being raised by the public.

National Association for the Study and Prevention of Tuberculosis, $1,000,000 donation from the American Red Cross.

Report on Antivenereal Campaign.—According to *Public Health Reports*, Jan. 3, 1919, all the states in the Union except Idaho, Michigan, Missouri, New Mexico, Pennsylvania, Tennessee and Utah, and the District of Columbia have complied with the provisions of the so-called Chamberlain-Kahn Act, which provides for a system of federal aid for antivenereal work in states meeting certain conditions. Several other states have signified their intention of cooperation in the near future. At the time of the report 125 clinics were being conducted in conjunction with state boards of health by the Division of Venereal Disease, United States Public Health Service, in which increasing numbers of cases were being treated each month, and additional clinics are demanded. In conjunction with the Red Cross twenty-five clinics are being conducted in extracantonment zones, with social follow-up work. Nurses especially trained and adapted for the work are needed. Five commissioned officers, forty-four acting assistant surgeons and three scientific assistants have been detailed to the various states as venereal disease control officers, and forty acting assistant surgeons have been on duty in the clinics in extracantonment zones. During the period of reconstruction it is expected that the work of venereal disease control will be broadened and intensified.

CANADA

Officers Wounded.—The following C. A. M. C. medical officers have recently been reported wounded: W. Hadden, Winnipeg; J. Burke, River Bourgeoise, N. S.; A. Warner, England; S. Cahille, Sydney, N. S.; J. A. Cooper, Souris, Man.; W. R. Copp, Blyth, Ont.; J. H. Daniel, Brantford, Ont.; J. Crowthers, Calgary; C. R. Deburgh, England; A. Millen, England.

Personal.—Capt. Donald C. Malcolm, M.D., St. John, N. B., and Capt. Finlay Munroe, C. A. M. C., Glengarry, Ont., have been awarded the Military Cross.——Dr. Albert G. Nicholls, professor of pathology and bacteriology, Dalhousie University, Halifax, who has been for three years fortress sanitary officer, in charge of the district laboratory of hygiene, has been appointed D.A.D.M.S. (Sanitation), M.D. No. 6, with rank as major.

University News.—The Medical Faculty of the University of Toronto had 255 students registered in the first year in medicine when it closed for the winter holidays.——Dalhousie University, Halifax, was closed for a month on account of influenza. The total entry into the faculty of medicine this session was 107.——Fifty new students were enrolled in the medical faculty of the Western University, London, Ont. The total attendance is about 100. The erection of a new medical school is contemplated.

Rewarded for Valor.—Among the members of the C. A. M. C., one has received the Victoria Cross; five have been made Companions of the Bath; sixteen, Companion of St. Michael and St. George; one, Knight Bachelor—Sir Andrew MacPhail, Montreal; one, Order of the British Empire (officer); two, Order of the British Empire (members); thirty, Distinguished Service Order; eighty-four, Military Cross; two, Bar to Military Cross; ninety, mentioned in dispatches; two, Croix de Commandeur; one, Croix de Officier; two, Croix de Chevalier; two, Croix de Guerre; one, Croix de Guerre (Belgium); one, Order of Saint Sava, Fifth Class, Serbia, Capt. Harry J. Shields, Toronto; Silver Medal for Military Valor, Italy, Capt. Howard H. Burnham, Toronto.

Public Health.—The Montreal Board of Health has created a special bureau of child hygiene. The energies of the new bureau will be devoted to reducing the infant mortality in that city which is about the highest in America.——A new medical bill is to come before the Ontario legislature at the coming session.——The Vancouver Medical Society is planning a state medical service. Medical supervision of the schools and the Workmen's Compensation Board will be coordinated with the new service.——The population of British Columbia is put down at 382,689, and 25,000 Indians. In the first six months of 1918 the deaths totaled 2,046; births, 4,940; marriages, 1,443. Tuberculosis was responsible for 236. Cancer showed an increase. In 1917 for the entire year cancer claimed 248, while in the first six months of 1918, the deaths were 144. The percentage of deaths from tuberculosis in the oriental population was 22.49.

GENERAL

Manpower Propaganda.—The United States Public Health Service has begun the work of sending out a series of pamphlets, folders, bulletins and leaflets prepared for the laity in the interest of personal and public hygiene, some of them having especial reference to the avoidance of venereal diseases. V. D. Bulletin 1, issued in cooperation with the Bureau of Education, Department of the Interior, bears the title "Keeping Fit," and treats of what is called the "four great handicaps"—defective eyesight, poor teeth, bad feet and venereal diseases. Other publications in the series are "When They Come Home," which has reference to venereal diseases, and "Venereal Disease, a Public Health Problem for Civilian Communities." This latter leaflet shows in graphic form that venereal diseases bear a relation to other communicable diseases of 102.3 to 29.4; also that venereal diseases among the troops bore a relationship of 5 before enlistment to 1 after enlistment, showing that the problem of venereal diseases is one of the civilian communities. A small pamphlet on "Manpower" treats of the sex question and venereal diseases.

FOREIGN

Hospital Opened at Archangel.—The American Red Cross announced, January 11, that it had established a base hospital of 100 beds at Archangel, Russia, and that eighty patients, almost all of them Americans, were under treatment in the institution.

Venereal Prophylaxis Urged by British Physicians.—In a letter to the London *Times* a number of physicians headed by Sir William Osler and including George Lenthal Cheatle, James Crichton-Browne, Bertrand Dawson, Bryan Donkin, David Ferrier, Rickman Godlee, Leonard Hill, F. W. Mott, G. Archdall Reid and James H. Sequeira, call for the adoption of measures for the prevention of venereal disease in the community following the discharge of soldiers from the Army. The final and the most important paragraph of the letter states:

> It has been abundantly proved during the war that venereal diseases can be controlled by the adoption of simple sanitary measures, the success of which is striking, and the materials for which can be obtained from any chemist. These measures should at once be made known and available, and organized instruction given in their application. This is the only effective way of meeting a dangerous situation—dangerous not only for our soldiers and sailors, but for the population at large. The danger of delay is very great.

Preventable Diseases in Spain.—Some recently published statistics are cited by the *Nuevo Mundo* of Madrid which show that during a recent month there were more deaths than births in nine leading cities of Spain, including Madrid. A serious epidemic of smallpox has been prevailing also at Ciudad Real, and the editorial comments on these facts saying, "Smallpox in the cities and the locust in the fields show the true stage of civilization which Spain has reached. With leprosy—which we also have in Spain and which seems to be increasing at an alarming rate—we have the same plagues and scourges as Morocco and Tartary. It would be absurd here to relate how Japan extinguished smallpox, exterminated it, banished it from the islands of Japan. It was a state campaign and it took five years. It would be absurd to relate either how the Yankees undertook the sanitation of Cuba and conquered yellow fever which has cost so many lives here in Spain. And yet many years have elapsed since the Spanish mandarins have been talking of a policy of sanitation."

CORRECTION

Minnesota News.—In The Journal, January 11, it was stated under "Minnesota News" that Dr. I. J. Murphy had located at Aitkin, Minn. We are informed by Dr. Murphy that he is at present taking postgraduate work in New York.

MEXICO LETTER

Mexico City, Jan. 12, 1919.

The Typhus Congress

January 14 will be the opening day of this scientific assembly for the purpose of studying typhus. It is to be held in the amphitheater of the Escuela Preparatoria, with Lic. J. N. Macias, the rector of the University, presiding. The president of the congress, Dr. José Terrés, will welcome the members, and Dr. T. G. Perrin will deliver an address. The general sessions will be held from the 15th to the 22d in the Escuela de Ingenieros.

Delegates have been appointed by the Academia de Medicina, the Departamento de Salubridad, the Facultad de Medicina and the governors of the different states of the Republic (11) and addresses will be presented and discussed bearing on the etiology, history, symptomatology, epidemiology, prophylaxis and treatment of tabardillo, or typhus, a disease which is endemic in this country and the exacerbations of which frequently cause a notable increase in the death rate. One of the points which it is expected will be debated with much variance of opinion is the question of the transmission of the disease by lice—as the sole or principal cause of the spread of the disease—as the prevalence of typhus among the well-to-do seems to be at least equal to its prevalence among persons habitually infested with lice, or at least certain clinicians claim to have observed this. The discussion of specific serotherapy, according to Nicolle and Blaizot, will also be one of the features of the meeting, as also the plan to found an institute for experimental research on Tabardillo.

Personal

Ing. Palavicini, who has recently returned from New York, has resumed charge of the daily paper, *El Universal*. He has written much on behalf of the Allies of the Entente, and in his propaganda he did not restrict himself to merely defending the justice of his cause, but proclaimed the urgent moral necessity for Mexico to line up with the forces defending right and justice in order to maintain its reputation as a liberal people. The *Universal* is to have a fortnightly section, to be entitled "Tribuna Medica" which will have the same character as the former Saturday "Medical Page."

Dr. Rafael Cabrera, physician and writer, has been appointed secretary of the Mexican legation in Italy.

At the request of the faculty of the University, Lic. A. Caso has been appointed director of the Escuela de Altos Estudios, of the University. Lic. Caso is a corresponding member of the Real Academia Española, member of the Society of Friends of France, and during the world conflict which has just come to an end, he defended with word and pen the ideals inspiring the nations leagued against Prussian autocracy. The Escuela de Altos Estudios includes in its courses, besides Greek, Latin and German, with French, English and Italian literature and other branches, ophthalmology, dermatology, gynecology, psychiatry, pediatrics, etc.

The Cold Wave

The weather recently has been intensely cold here, something to which we are not accustomed. The mercury registered 17.6 F. (8 below zero C.). So far as I have been able to learn, this drop in the temperature has not affected the morbidity but it is reported from San Luis that one person died from the cold there.

BUENOS AIRES LETTER

Buenos Aires, Dec. 7, 1918.

Influenza

The epidemic which started here October 20 rapidly declined in November, having lasted about twenty-five or thirty days. From 25 to 70 per cent. of the people in different districts were affected. The mortality was rather low, about 1,000, that is, averaging thirty deaths daily for a population of 1,600,000 inhabitants. The new dean of the Facultad de Medicina organized some scientific meetings for discussion of the epidemic; they were attended by students and the public in numbers but not so much by the professors and practitioners. Dr. Penna related that there were forty-nine deaths among the 404 cases in his charge, but he added that the pneumonia cases were mostly directed to his service. Of 132 cases with pulmonary complications, forty-eight terminated fatally. He called attention to a few rare cases with petechial spots. Dr. Llambias reported that the anatomic findings included parenchymatous lesions in various organs and general hemorrhagic phenomena in the serosas and in some of the organs. The microscope showed that the lesions were of the pneumonic type, but atypical. In some cases there seemed to be a lack of fibrin.

Dr. Julio Mendez presented some views which were evidently revolutionary but were not sustained by convincing proofs. He affirmed that the causal agent of influenza is the pneumococcus and that the streptococcus and the Pfeiffer bacillus are simple modifications of the pneumococcus. He advocated the use of a vaccine which he prepares, entitled haptinogeno neumo, the composition of which has not been made public.

A meeting was held at the Instituto Bacteriologico of the Departamento Nacional de Higiene, November 23, at which Dr. Kraus reported that he had found the Pfeiffer bacillus in the sputum in 62 per cent. of the cases of influenza. It was alone in about half the cases and associated in the others with the pneumococcus, streptococcus and parameningococcus. The Pfeiffer bacillus was found in the organs in seventeen of the twenty-seven who had died; it was in pure culture in five, and associated with other bacteria in the others. In the other ten cases he found only the streptococcus and pneumococcus.

LONDON LETTER

London, Jan. 1, 1919.

An Association of the Physicians of the English-Speaking Countries

During the war an enormous number of physicians from the English-speaking countries—America and the Dominions—have passed through and sojourned in England. The British profession and its medical societies have offered them every hospitality. At the house of the principal medical society—the Royal Society of Medicine—the medical officers of the Dominions, America and the Allies have been cordially invited to consider themselves at home and use the library and other rooms. Some hospitality has been shown to the visitors every day by offering them tea, coffee and cigarets between 4 and 6 in the afternoon. At all the military commands throughout the country, medical officers from overseas have been cordially invited to attend clinics, lectures and demonstrations, and in some cases arrangements have been made for systematic courses and elaborate syllabi issued. These facilities have been much appreciated by the visitors. Out of these meetings, which have been a source of pleasure both to hosts and to guests, has grown a movement for forming an association for cooperation in medicine of the English-speaking countries, but not limited to them. Sir Arbuthnot Lane presided over a meeting at the Royal Society of Medicine to further this object. Among those present were Major J. H. Means (United States), Lieutenant-Colonel Castellani (Italy) and Professor Weinberg (Paris). Sir St. Clair Thomson and Mr. J. Y. W. MacAlister (secretary of the Royal Society of Medicine), acting honorary secretaries appointed at a previous meeting, submitted their report. It had been urged that the opportunity presented by the coming together of physicians from America and all parts of the British Dominions should be utilized to form some permanent organization which would result in a closer union between the English-speaking peoples through the medium of the medical profession. A circular setting out these aims was sent to the chiefs of the medical forces of this country, of the Dominions, and of America, and cordial expressions of approval and promises of support were received. The Royal Society of Medicine has given a room for an office which may now be regarded as the headquarters of the association. All the principal London hospitals were communicated with, and in practically every case they cordially responded and invited overseas visitors to come to the hospitals and attend lectures and operations. In the entrance hall a special notice board is placed calling attention to what is going on. Sir St. Clair Thomson, in seconding the adoption of the report, urged that in addition to a bureau of information it was desirable to establish individual and personal cooperation, and that volunteers should offer to take personally conducted parties to hospitals, museums and other medical institutions. Such cooperation would be very effective in creating a permanent entente. A general committee was nominated, and Sir Arbuthnot Lane was appointed honorary treasurer, and Sir St. Clair Thomson, Mr. Douglas Harmer, and Mr. J. Y. W. MacAlister honorary secretaries (pro tempore).

Medical Demobilization

The demobilization of the civilian physicians serving as medical officers in the navy, the army and the air force will be arranged through the Ministry of National Service. Until the general demobilization of the forces begins, the number of medical officers to be demobilized must remain strictly limited; and in view of the serious shortage of physicians in many parts of the country, the officers to be released first must be those whose return to civil practice will maintain and strengthen the medical service of those areas. As soon as general demobilization begins, medical officers will be demobilized on a scheme of priority based on both public and personal grounds; and in order to enable every case to be fully considered, steps are being taken to obtain the necessary information from every serving medical officer. To expedite the release of medical officers who have been on service for a long period and are urgently required at home, the Minister of National Service has decided that newly qualified physicians and medical students who have been protected from recruiting in order to obtain their degree will, as they qualify be called up for service as medical officers, and will continue to serve in this capacity until their services are no longer required, owing to the approaching completion of demobilization, when they will in turn be demobilized.

The Central Medical War Committee has for some time past been considering the various ways in which physicians returning from the services may be assisted to reestablish themselves in civilian practice. A conference on this subject was held between members of the committee and representatives of several benevolent societies, such as the Officers' Families Fund, the National Relief Fund, the War Emergency Fund of the Royal Medical Benevolent Fund, the Professional Classes War Relief Fund, the Committee of Reference, and the Appointments Department of the Ministry of Labor. The object was to discuss the possibilities of giving financial aid (by loan or grant) in the resettlement of physicians, and of cooperation between the various funds. A letter was addressed by the Committee to the War Office, the Ministry of Pensions, the Ministry of National Service, and the Local Government Board suggesting that physicians returning from military service should be given preferential treatment in the large amount of medical work of a military or national character that will be available throughout the country. Some of the work will be new; some of it has been carried out during the past few years by civilian physicians. The committee is of opinion that the authorities concerned should as soon as possible make widely known their intention to give these posts to physicians returning from service whose military experience has familiarized them with the kind of work to be done. With regard to the duties that have been performed up to the present by civilian physicians, the committee holds that when these have been carried out by a rota of physicians, the returned physician should be placed on the rota immediately he applies, and work given to him should he desire it, if necessary by relieving civilian physicians. If accepted, these suggestions will go far to assist the returned physicians during the first few critical months after their release, and will in addition do much to convince them that during their absence they have not been forgotten.

Postgraduate Teaching After the War

The crimes committeed by the Central Powers during the war have by no means been merely the acts of governments but have been zealously carried out by their soldiers and applauded by their peoples. They have never been repudiated by any class, even by scientists of international reputation, and the medical profession has been guilty of shocking inhumanity to prisoners. Both in this country and in France, leading scientific men have stated that they cannot cooperate with men in enemy countries for some years, and the same feeling prevails in the medical profession. It is therefore likely that the position occupied by Berlin and Vienna as centers of postgraduate instruction will be lost. Professor Adami has expressed the view that Paris will probably become the chief center of postgraduate instruction in Europe, as the French were making every endeavor to achieve this. While in England no one will grudge our gallant allies any success, but on the contrary every one will rejoice in it, much dissatisfaction is felt that no organized attempt is being made to advance the claims of London. The fundamental difficulty is that, excepting ophthalmology and neurology, there is no centralization of medical teaching such as exists in the enemy capitals, and facilities are organized almost entirely for the teaching of students. The difficulty appears to be insuperable. London, it has been said, is not a city but a monster—a conglomeration of many districts equal to cities. As is characteristic of English institutions, the hospitals are the result of private effort and not of government organization. Each of the dozen great London general hospitals with teaching schools attached has grown up and is maintained by private beneficence. Each is a complete medical school devoted to the instruction of students, and is as independent of all others as if they were hundreds of miles away. Scattered through these medical schools are the men whose names are famous throughout the world, but nowhere are they brought to a focus. The foreign graduate who comes here interested in some specialty cannot find any central institution where he can follow all that has been done in that particular line. Even the special hospitals are multiple. There is no university in London devoted to medical teaching, such as centralizes the medical teaching of Edinburgh and has long given that city a leading position among the medical schools of the empire. Attempts have been made from time to time to organize postgraduate teaching in London, but with little success. The last attempt, the Polyclinic, did good service for a few years, but was always in financial difficulties. These were so accentuated by the war that it had to close its doors.

PARIS LETTER

Paris, Dec. 12, 1918.

Interallied Surgical Conference

The interallied surgical conference for the study of war wounds held its fifth session at the Ecole d'application de médecine et de pharmacie militaires at Val-de-Grâce, November 18-21. The subjects discussed were: anesthesia in war surgery; antigangrene serum therapy; treatment of projectile wounds of the hip joint, kidney and hand, as well as the immediate and remote results of the treatment of arteriovenous aneurysms.

TREATMENT OF PROJECTILE WOUNDS OF THE HIP JOINT

The usual treatment employed in wounds of joints is also indicated in cases of wounds of the hip joint. The prognosis is not as good in these cases, however, as in the case of other joints because of the depth of the articulation, which is unfavorable for early diagnosis, for operative intervention and for drainage in infected cases. Wounds of the joint without bone lesions, or with only slight bone lesions, recognized early, justify an ideal arthrotomy: excision of the track of the projectile, incision of the capsule, evacuation of the blood, removal of foreign bodies, curettage of the bone lesion, cleansing the wound and suture. A comminuted intracapsular fracture seen early may be treated by a resection through the neck, removing as little bone as possible. An extracapsular fracture, with fissures extending into the joint, should be treated like any other extracapsular fracture: removing only such fragments as should be removed, cleansing the wound carefully, with chemical disinfection or tamponade, and secondary suture. When there is suppuration with either an intra or extracapsular fracture, immediate resection of the articular end of the femur is indicated. The postoperative care, especially the position of the limb and its immobilization, is of very great importance. It is of advantage to have the patient walk as soon as possible with the assistance of various orthopedic apparatus. The results, so far as life are concerned, are good in the primary resections and the deferred secondary resections; they are much more uncertain in the early secondary intrafebrile resections. The functional results are in accord with the time of the resection and the amount of bone removed: in general, they are very good for the intracapsular resections, and less favorable in the transtrochanteric or subtrochanteric resections.

PROJECTILE WOUNDS OF THE KIDNEY

When the local signs, the general symptomatology and the roentgenoscopic examination point to some lesion of the kidney only, without involvement of any other organs, operation should not be performed in the following cases: (1) When the projectile has made merely a seton wound or remains enclosed and is of small size; (2) when hematuria is not abundant and lessens progressively each day after the injury; (3) in the absence of a large perirenal hematoma which is not discoverable by an intumescence in the lumbar region. In all other cases it is advisable to operate.

The indications for nephrectomy, partial or complete, are: menacing primary hemorrhage; repeated secondary hemorrhages; grave infections. At the time of operation, the conservation or removal of the kidney will depend on the state of the kidney parenchyma. Before resorting to nephrectomy, the state of the other kidney should be known as positively as possible.

When some other intra-abdominal organ is injured, a lateral or median laparotomy is performed, following the track of the projectile. Subsequent procedures will be dictated by the results of examination of the renal region. In cases of thoraco-abdominal wounds, the lung and kidney must be treated separately, profiting as much as possible from a single wound of entrance, closing the diaphragmatic wound carefully to isolate the two foci.

In cases of kidney wounds not only the local lesion must be considered, but also the necrosis which may follow in the territory supplied by the blood vessels in the region of the hilus and of the parenchyma. The function of an injured kidney which has been treated conservatively, tends to reestablish itself, provided that infection can either be prevented or checked.

PROJECTILE WOUNDS OF THE HAND

Wounds of the hand are treated in the same manner as all other war wounds. Conservative methods should be pushed to the furthermost limit. Immediate operations should, preferably, be economical operations, making for union by first intention, with surgical repair of tendons and nerves. A limited bone resection may be done to obtain a soft scar and a good position. The quality of the scar as well as the mobility of the tendons and of the joints are of more importance than complete conservation of the bony skeleton. During cicatrization, the wounded zone should be immobilized in a good position, but immediate motion, active and passive, of all sound parts, and the early mobilization of the injured part or region, are important. After cicatrization, it is, again, mobility that must be obtained. The lesions of the phalanges and phalangeal joints are treated in the same manner as are injuries of the larger bones and joints of the members, that is to say, by removal of bone fragments and primary suture or early secondary suture. In the case of the thumb, resection of the joint is preferable to amputation. Whenever there is present the possibility that a finger is destined to become completely stiff, without any chance for motion, amputation should be done. Resection of the head of the corresponding metacarpal is always indicated after disarticulation of the index or little finger. In cases of fracture of a metacarpal, total esquillectomy is indicated, preferably through the back of the hand. In carpal-metacarpal lesions, resection is generally limited to the affected bones. Division and loss of parts of tendons are treated in the usual manner, varying with the site and extent of the lesion. Adhesions following tendon surgery are the greatest obstacle to motion. Immediate and continuous motion will do much to avoid this complication. In cases of extensive injury of the metacarpal region, high amputation of the metacarpals is preferable to disarticulation at the wrist.

IMMEDIATE AND REMOTE RESULTS OF THE TREATMENT OF ARTERIO-VENOUS ANEURYSM

Arterio-venous aneurysms, except in rare instances, do not heal spontaneously. Surgical intervention is indicated because of the complications which may eventually develop later, especially in the legs. Operation should be delayed for at least two months, unless immediate intervention is demanded by rapid increase in size or aggravation of the functional disturbances. The ideal operation consists in separation of the two vessels and lateral suture of the connecting openings in each. When the opening in either vessel is larger than half of its circumference, and if the involvement of the vessel wall does not exceed 3 cm. in length, resection and end-to-end suture is the method of choice. When a conservative operation cannot be done, extirpation of the aneurysm, that is, the union of the two vessels, is the best method of treatment. If neither of these procedures can be carried out, then ligation of each vessel above and below the aneurysm, (four ligatures) is indicated.

Centralization of Reconstruction Work

The Office national des mutilés et réformés de la guerre, which was established in 1918 (The Journal, June 8, 1918, p. 1784), recently held its official meeting at the ministry of labor. M. Henry Chéron, president of the administrative committee, explained the work of the committee since its foundation, the organization itself, etc. Dr. Queuille presented a report on the results obtained by the schools for professional reeducation of the maimed, and on the reforms brought about and the formation of new centers.

The assembly discussed and voted the budget for 1919 in which were embodied the credits necessary for the constitution of departmental and local committees, for the maintenance of the schools of professional reeducation and the establishment of new schools, and funds to be advanced to the maimed and invalided, after training, for the purpose of enabling them to gain a foothold in their new field of activity.

Medical Students and Demobilization

Dr. Louis Mourier, undersecretary of state for the Service de Santé militaire, has laid down the following rules for the demobilization of medical students: "We have never ceased to claim of the Etat-Major all those students possessing credits in physics, chemistry and natural sciences, although the commandant was unwilling to let us have any students except those who had several inscriptions of the doctorate, two, for example. Now that the armistice has been signed, the demands of the high command have lost much of their value and we hope to be able to secure in the near future all the students of the class of 1916 (22 years of age) and preceeding years who have the necessary credits in physics, chemistry and natural sciences and two inscriptions of the doctorate. Most of these men have already been sent to Bordeaux, Lyon and Paris to become *médecins auxiliaires*. They remain subject to their military obligations, but they will go on with their medical studies in these university centers. The signing of the armistice makes it possible to send a larger number of the students back to the cities, where are the faculties and the schools in which they were enrolled. In the morning they are required to care for the sick and wounded who are still under treatment in the military hospitals. In the afternoon they take up the practical work pertaining to their medical studies. It is desired that during the year 1919 they can complete in six months a whole year's work in medicine. These students will be assigned to this work in successive groups. The system will no doubt be in full operation by February 1. These measures will meet the medico-military needs which must be met until such time as all classes of the reserve are demobilized, and also are to the best interests of the medical corps."

Training School for Nurses for the Tuberculous Poor

A special subscription was opened in London for the Société de secours aux blessés militaires (one of the three societies forming the French Red Cross) for the purpose of enlarging one of its hospitals into a training school for nurses to care for the tuberculous poor, and to endow this establishment with all modern hygienic accessories. The sum of 450,000 francs has already been subscribed and handed over to the Lyons branch of the Société de secours aux blessés militaires.

Franco-American Friendship

The students of the University of Lyon recently tendered a reception in the large amphitheater of the medical faculty to the American medical students among the troops in the cantonments of that region. The highest local authorities were present in honor of the occasion—the military governor, the mayor, the rector and professors of the university and the consuls of the allied nations. Addresses were delivered by MM. Bernard, president of the Association générale des étudiants; Joubin, rector of the university, and Mayor Herriot, who rendered homage to the noble character of President Wilson, and invited the American students to come in numbers to the University of Lyon, where a most cordial welcome awaits them.

Personal

At a meeting held December 16, the Académie des Sciences elected Mr. David Bruce of London, England, a corresponding member of the section on medicine and surgery.

Deaths

George Grant Gere, San Francisco; Eclectic Medical Institute, Cincinnati, 1871; aged 70; a veteran of the Civil War; professor of anatomy from 1881 to 1886, and of surgery from 1886 to 1906, in the California Medical College; formerly president of state and vice president of national eclectic medical societies, and secretary of the state board of medical examiners; visiting surgeon to the San Francisco City and County Hospital, a member of the staff of the Balboa Hospital and supreme surgeon of the Royal Knights of America; died at his home, December 29, from lobar pneumonia.

Clyde Lorenzo Carey ⊕ Lieut., M. C., U. S. Army, Elmira, N. Y.; University of Buffalo N. Y., 1910; aged 34; president and formerly secretary of the Chemung County Medical Society; who was discharged from the Army, December 18; died at his home, January 6, from pneumonia. A special meeting of the Chemung County Medical Society and Elmira Academy of Medicine was held in the room of the latter organization, January 8, at which resolutions were adopted regarding the death of Dr. Carey.

Robert Lord Hull ⊕ Major, M. C., U. S. Army, Oklahoma City; Jefferson Medical College, 1902; aged 43; associate professor of orthopedic surgery in the University of Oklahoma, Norman and Oklahoma City; chief surgeon of the Emergency and St. Anthony hospitals, Oklahoma City; on duty as head of the orthopedic department at Letterman General Hospital, Presidio, San Francisco; died in that institution, January 5, from pneumonia following influenza.

Frank Wyman Lamb, Akiak, Alaska; Detroit Homeopathic College, 1908; aged 31; owner of a private hospital at Akiak; a member of the commission of surgeons named by the territorial government of Alaska, to combat influenza; for four years a member of the commission appointed by the board of education to aid in promoting health conditions among the children of Alaska; died at Old Hamilton, at the mouth of the Yukon River, December 23, from influenza.

John McMaster Ristine ⊕ Cedar Rapids, Iowa; Bellevue Hospital Medical College, 1876; aged 71; consulting surgeon to St. Luke's Hospital; a member of the American Association of Railway Surgeons; district surgeon to the Chicago and Northwestern, Rock Island and Illinois Central systems; one of the most prominent practitioners of central Iowa; died at his home, January 9, from heart disease.

Herbert Martin Howes ⊕ Capt., M. C., U. S. Army, Portland, Me.; Bowdoin Medical School, Brunswick and Portland, 1917; aged 28; an intern in the Maine General Hospital, Portland; and assistant professor of pathology in his alma mater; who was discharged from the Medical Corps of the Army, December 21; died in Brunswick, Me., January 5, from pneumonia following influenza.

Samuel Leo Oren ⊕ Lieut., M. C., U. S. Army, Lewistown, Ill.; Barnes Medical College, St. Louis, 1899; aged 39; a specialist on diseases of the eye, ear, nose and throat; who after a course of training at Fort Oglethorpe, Ga., was sent overseas; died in France, October 9, from nervous collapse presumably following ambulant typhoid fever.

Herbert Leer McNeil ⊕ Lieut., M. C., U. S. Army, Houston, Texas; Johns Hopkins University, Baltimore, 1911; aged 32; associate professor of medicine and clinical pathology in the University of Texas, Galveston; on duty with the American Expeditionary Forces, in Camp Hospital No. 30, France; died, November 3, from bronchopneumonia.

Charles Henry Weintz ⊕ Capt., M. C., U. S. Army, Cincinnati; Maimi Medical College, Cincinnati, 1909; aged 33; a specialist in diseases of the eye, ear, nose and throat; assistant chief of the nose and throat department of the base hospital, Camp Sherman, Chillicothe, Ohio; died at Camp Sherman, October 14, from pneumonia.

Louis Becker, Knoxville, Ill.; Northwestern University Medical School, Chicago, 1888; aged 54; a member of the Illinois State Medical Society; physician in charge of the Knox County Almshouse and Insane wards; and physician to St. Mary School and St. Albans Academy, Knoxville; died at his home, about January 5.

Carl Edward Holmberg ⊕ Lieut.-Col., M. C., U. S. Army, Whipple Barracks, Ariz.; Jefferson Medical College, 1908; aged 39; commanding officer of U. S. Army General Hospital No. 20, Whipple Barracks, Ariz.; who entered the Medical Corps of the Army, Sept. 1, 1909; died in that institution, January 1, from pneumonia.

⊕ Indicates "Fellow" of the American Medical Association.

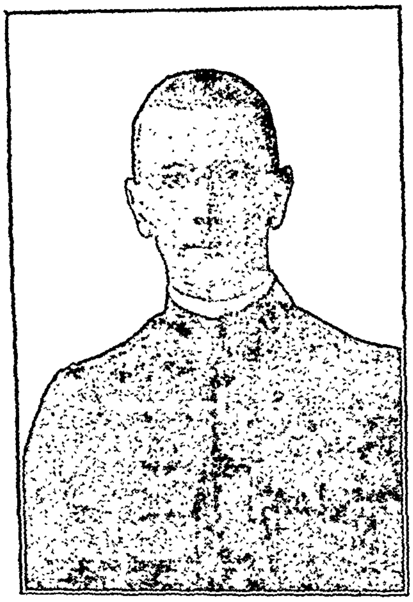
William A. Allen, Donnellson, Ill.; Missouri Medical College, St. Louis, 1878; aged 62; a member of the Illinois State Medical Society; one of the organizers and president of the State Bank of Donnellson; died in St. Francis' Hospital, Litchfield, Ill., January 5, from septicemia due to scratch of the right index finger.

Joseph Alphonse Furlong ⊕ **Lieut., M. C., U. S. Army,** Spring View, Neb.; St. Louis University, 1912; aged 29; on duty with the American Expeditionary Forces in France; while returning from leave spent in Ireland, was killed off Kingstown, Ireland, by the torpedoing of the steamship *Leinster*, October 10.

Frank Watson Jackson ⊕ New York City; College of Physicians and Surgeons in the City of New York, 1879; aged 63; a fellow of the New York Academy of Medicine; consulting physician to Bellevue and Roosevelt hospitals; professor of clinical medicine in his alma mater; died at his home, January 8.

George M. Clouse, Columbus, Ohio; Columbus (Ohio) Medical College, 1890; aged 57; president of the Practitioners' Medical Society; one of the founders of the Ohio State Pediatric Society; professor of diseases of children in the Ohio University; died at his home, January 5, from heart disease.

Jerome McKaig Leonard ⊕ **Lieut., M. C., U. S. Army,** Douglas, Ariz.; Hahnemann Medical College, Chicago, 1906; aged 34; on duty with the American Expeditionary Forces in France; is reported to have been killed in action in France, November 8.



Died in the Service
IN FRANCE
LIEUT. JEROME MCKAIG LEONARD,
M. C., U. S. ARMY, 1884-1918

Davis Neeper Richards ⊕ **Lieut., M. C., U. S. Army,** Germantown, Md.; Johns Hopkins University, Baltimore, 1915; aged 28; on duty with Evacuation Hospital No. 49, American Expeditionary Forces, since June, 1918; died at Camp Merritt, N. J., October 12, from bronchial pneumonia following influenza.

John Edwin Ray, Jr. ⊕ **Capt., M. C., U. S. Army,** Raleigh, N. C.; Cornell University, New York City, 1912; aged 31; a specialist in surgery; on duty with the American Expeditionary Forces in France; died, October 5, from wounds received in action in Bellicourt, September 22.

William Marks Lewis, Sharon, Pa.; College of Physicians and Surgeons, Baltimore, 1892; aged 57; a member of the Medical Society of the State of Pennsylvania; died, December 30, from heart disease on a Pennsylvania train between New Brighton and New Castle, Pa.

James Francis Gorman ⊕ **Lieut. (j. g.), U. S. N. R. F.,** Manchester, Conn.; Georgetown University, Washington, D. C., 1911; aged 34; who had been on duty at the Brooklyn Navy Yard; died at his home in Manchester, December 28, from pneumonia following influenza.

William D. Donne, North Scranton, Pa.; Western Pennsylvania Medical College, Pittsburgh, 1888; aged 55; also a pharmacist; for three years outdoor physician for the poor; and until recently a member of the staff of the Farview Hospital; died at his home, January 8.

John Victor Bean ⊕ Fairfield, Iowa; Bellevue Hospital Medical College, 1868; aged 75; acting assistant surgeon, U. S. Army, in 1868 and 1869; lecturer on sanitary science in Parsons College, Fairfield; city health officer of Fairfield; died at his home, January 7.

Horace Melville Simmons ⊕ Baltimore; University of Maryland, Baltimore, 1881; aged 64; associate editor and part owner of the *Medical Review of Reviews;* founder and owner of the *Maryland Medical Journal;* died suddenly at Mountain Lake, N. J., January 5.

Joseph S. Herndon, Ashland, Ore.; Willamette University, Salem, Ore., 1874; aged 70; at one time a member of the Oregon State Medical Association; was run over and killed by a locomotive in the railroad yards at Roseburg, Ore., December 6.

Mitchell Mikkelsen ⊕ Wells, Minn.; College of Physicians and Surgeons, Keokuk, Ill., 1877; University of Illinois, Chicago, 1884; aged 68; a specialist in diseases of the eye, ear, nose and throat; died at his home, January 8, from pneumonia.

Stanley Lee Cassell ⊕ **Lieut., M. C., U. S. Army,** Sweet Grass, Mont.; University of Illinois, Chicago, 1914; aged 28; on duty with the American Expeditionary Forces in France; was killed, November 4, at Earle Fontaine, France, by shell explosion.

Joseph N. Eldred, Chesaning, Mich. (license, Michigan, years of practice, 1900); aged 81; a member of the Michigan State Medical Society; a practitioner for fifty-eight years; also a druggist; died at his home, December 20, from senile debility.

Lester Linwood Schwab ⊕ Benson, Ariz.; University College of Medicine, Richmond, Va., 1900; aged 40; who after sixteen years' practice in Roanoke, Va., went to the Southwest in 1916, in search of health; died at his home, December 28.

Benjamin Franklin Hawn, Youngstown, Ohio; Bellevue Hospital Medical College, 1873; aged 61; was killed in Youngstown, December 22, when his automobile was struck by a New York Central train at a grade crossing.

Elmer T. Bunten, Flemingsburg, Ky.; Kentucky School of Medicine, Louisville, 1907; aged 35; a member of the Kentucky State Medical Association; died at his home, November 9, from bronchial pneumonia following influenza.

Robert Eldridge Hearn ⊕ **Lieut., M. C., U. S. Army,** Mabank, Texas; University of Louisville, Ky., 1904; aged 39; on duty at the camp hospital at Camp Funston, Leon Springs, Texas; died, October 18, from bronchopneumonia.

Stewart Wiley Pryor ⊕ Chester, S. C.; Atlanta (Ga.) Medical College, 1887; aged 54; owner of the Pryor Hospital, Chester, and a well-known surgeon of upper South Carolina; died at his home, December 27, from pneumonia.

Elmer Ellsworth Lenhardt, Millersville, Pa.; Temple University, Philadelphia, 1909; aged 35; a member of the Medical Society of the State of Pennsylvania; died at his home, October 6, from pneumonia following influenza.

Ella T. Colby, Roads, Mo.; St. Louis Woman's Medical College, 1895; aged 51; a member of the Missouri State Medical Association; died in the Kansas City (Mo.) Research Hospital, November 3, from pernicious anemia.

Casper Joseph Middlekauff ⊕ **Lieut., M. C., U. S. Army,** Hayes, Kan.; Jefferson Medical College, 1917; aged 31; on duty with the American Expeditionary Forces in France; died in France, October 8, from pneumonia.

John Comas Matthews ⊕ Springfield, Mo.; Missouri Medical College, St. Louis, 1890; aged 53; local surgeon of the Missouri Pacific System; and formerly coroner of Green County; died at his home, December 7.

Peter Sylvester MacDonald ⊕ Chicago; Rush Medical College, 1864; aged 82; for several years professor of anatomy in the Northwestern University Woman's Medical School, Chicago; died at his home, January 20.

Robert L. Roll, Kirkmansville, Ky.; University of Louisville, Ky., 1893; aged 47; a member of the Kentucky State Medical Association; died in the Jennie Stuart Hospital, Hopkinsville, December 30, from arteritis.

Samuel Dana Henderson ⊕ **Lieut., M. C., U. S. Army,** Lansford, N. D.; Tulane University, New Orleans, 1916; aged 30; died in Camp Greenleaf, Fort Oglethorpe, Ga., October 19, from pneumonia following influenza.

Benjamin F. B[illegible]s, Altoona, Pa.; Hahnemann Medical C[illegible] 1883; aged 59; formerly president of t[illegible]meopathic Society; died in Colorado Springs, December 22, from asthma.

Clarence Frederick Rulmann, Minster, Ohio; Ohio State University, Columbus, 1915; aged 28; a member of the Ohio State Medical Association; died at his home, October 19, from pneumonia following influenza.

Burgess Allen Gibson ⊕ **Lieut., U. S. Army,** Washingtonville, Pa.; Jefferson Medical College, 1913; aged 30; is reported to have died in France, November 3, from the effects of wounds received in action.

George P. Smartt, Manor, Texas; Baylor University, Dallas, Texas, 1905; aged 38; a member of the State Medical Association of Texas; died in Austin, Texas, December 26, from pneumonia following influenza.

Thomas Hays, Deland, Fla.; Albany (N. Y.) Medical College, 1881; aged 90; for many years a practitioner of Clearfield Corners, N. Y.; died at the home of his son in Deland, December 27, from pneumonia.

Gerald J. Fitzgibbon ⊕ San Francisco; Cooper Medical College, San Francisco, 1877; aged 63; died in St. Francis' Hospital, San Francisco, January 10, from bronchial pneumonia following influenza.

Quincy A. Tipton, Cottonwood Point, Mo.; University of Louisville, Ky., 1877; aged 74; a member of the Missouri State Medical Association; died at his old home in Blytheville, Ark., November 11.

Arthur Robert Ohman, Chicago; University of Illinois, Chicago, 1913; aged 27; a member of the Illinois State Medical Society; died at his home, January 11, from pneumonia following influenza.

Laurence Joseph Simonton, Cumberland, Md.; George Washington University, Washington, D. C., 1909; aged 38; a specialist in urology; died at Centerville, Pa., October 10, from tuberculosis.

Oliver Austin Everett, Bolton, Mass.; Dartmouth Medical School, Hanover, N. H., 1885; aged 58; for twenty-three years postmaster of Bolton; died at his home, January 2, from influenza.

Albert Wilson Nash ⊕ North Haven, Me.; Bowdoin Medical School, Brunswick and Portland, Me., 1895; aged 47; died at his home, December 3, from empyema following pneumonia.

Nancy Maria Hill, Dubuque, Iowa; University of Michigan, Ann Arbor, 1874; aged 85; a volunteer nurse for three years during the Civil War; died in Finley Hospital, Dubuque, January 8.

Thomas M. Thayer, Herman, Minn.; New York Homeopathic Medical College, New York City, 1900; aged 42; died at his home, December 22, from pneumonia following influenza.

Clyde Everett Shedd ⊕ **Lieut., M. C., U. S. Army,** San Francisco; Oakland (Calif.) College of Medicine and Surgery, 1917; aged 25; was killed in action in France, October 16.

Julius Lewis Shryer ⊕ **Lieut., M. C., U. S. Army,** Durant, Iowa; Chicago College of Medicine and Surgery, 1917; aged 29; died from bronchial pneumonia in France, November 4.

Frank Philip Schneider, Rochester, N. Y.; Albany (N. Y.) Medical College, 1916; aged 28; died at a hospital in Rochester, December 31, from rheumatic endocarditis.

Robert H. Bradley ⊕ Marshall, Ill.; Northwestern University Medical School, Chicago, 1873; aged 74; died in his office at Marshall, January 4, from heart disease.

William W. Cunningham, Offerle, Kan.; University of Louisville, Ky., 1908; aged 37; died at Spearsville, Kan., December 2, from pneumonia following influenza.

Frederick W. Schneerer, Norwalk, Ohio; Eclectic Medical Institute, Cincinnati, 1875; aged 68; died at his home, about December 22, from pneumonia following influenza.

John A. Ferguson ⊕ Sault Ste. Marie, Mich.; Detroit College of Medicine and Surgery, 1903; aged 43; died at his home, October 4, from valvular heart disease.

Chauncey Macaulley Marstin, Braintree, Mass.; Howard University, Washington, D. C., 1880; aged 73; a veteran of the Civil War; died at his home, January 6.

Prince Edwin Luce, Brooks, Me. (license, Maine, Act of 1895); aged 60; died at the home of his sister in Clinton, Me., December 13, from cerebral hemorrhage.

Virginia Harley McKnight ⊕ Fair Haven, N. Y.; University of Michigan, Ann Arbor, 1873; aged 77; died at her home, December 28, from heart disease.

Madison Canaday, Eugene, Ore.; a practitioner for fifty years; aged 87; died at the home of his daughter in Crow, Ore., December 14, from senile debility.

Marie M. Simons Romine Perfect, Columbus, Ohio; Woman's Medical College of Cincinnati, 1894; aged 49; died at the home of her mother, January 2.

Antoinette K. Fellows, Chicago; Hering Medical College, Chicago, 1896; aged 73; died at her home, January 5.

Charles Joseph Turvey, Albuquerque, N. M.; North Carolina Medical College, Charlotte, 1910; aged 32; died in Albuquerque, recently, from tuberculosis.

Benjamin P. Wilson, Lake Butler, Fla.; Charity Hospital Medical College, New Orleans, 1876; aged 68; died at his home, December 17, from nephritis.

James Monroe Rainey, Chicago; Eclectic Medical Institute, Cincinnati, 1893; aged 51; died in a sleeping car between Omaha and Chicago, December 30.

Mathew Brinkerhoff DuBois, New York City; College of Physicians and Surgeons in the City of New York, 1868; aged 77; died at his home, December 29.

Elmer Roscoe Cravens, Linton, Ind.; Kentucky School of Medicine, Louisville, 1888; aged 56; died at his home, January 6, from cerebral hemorrhage.

Otho E. Francis, Dayton, Ohio; Kentucky School of Medicine, Louisville, 1878; aged 68; died in the Miami Valley Hospital, Dayton, December 31.

William E. Trueblood ⊕ Fairfield, Calif.; Physio-Medical College of Indiana, Indianapolis, 1897; aged 52; died in Oakland, Calif., December 29.

Jeremiah D. Phelan, Brooklyn; Long Island College Hospital, Brooklyn, 1883; aged 57; died in St. Peter's Hospital, Brooklyn, January 2.

Joseph Azel Knox, Whiteside, Mo.; Washington University, St. Louis, 1865; aged 79; died at his home, December 25, from senile debility.

Albert Claypool, Toledo, Ohio; New York Homeopathic Medical College, New York City, 1876; aged 72; died at his home, December 30.

Solomon P. Stoddard, Indianapolis; University of Heidelberg, Germany, 1863; aged 77; died at his home, December 22, from influenza.

Sidney Wells Johnson, Akron, Ohio (license, years of practice, 1897); aged 73; a veteran of the Civil War; died at his home, January 6.

Homer Curtis Potter ⊕ Des Moines, Iowa; Eclectic Medical Institute, Cincinnati, 1855; aged 84; died at his home, December 24.

Melville M. Moffitt, Washington, D. C.; Homeopathic Hospital College, Cleveland, 1882; aged 61; died at his home, December 29.

George Granville Monroe, Chicago; University of Michigan, Ann Arbor, 1878; aged 66; died at his home, January 8, from uremia.

William Orson Congdon ⊕ Cuba, N. Y.; University of Vermont, Burlington, 1896; aged 69; died at his home, October 18.

Theodore Kiss, Jr., Trenton, N. J.; University of Budapest, Hungary, 1894; died at his home, January 4, from cerebral hemorrhage.

Charles H. Brunk, Windsor, Ill.; Rush Medical College, 1865; aged 93; died at his home, January 4, from senile debility.

Edward Patrick Ryan, St. Paul; Rush Medical College, 1886; aged 54; died at his home, December 31, from heart disease.

Walter Howland Squires ⊕ Roulette, Pa.; Jefferson Medical College, 1899; died at his home, December 6.

Samuel H. Pettigrew, Springdale, Pa.; Jefferson Medical College, 1872; died at his home, January 1.

Robert R. Freeman, Tucson, Ariz.; Vanderbilt University, Nashville, Tenn., 1875; died recently.

Marriages

EDWARD FREDERICK MEISTER, Lieut., M. C., U. S. Army, Buffalo, to Miss Mabel C. Hope of Walthamstow, Essex, England, November 24.

GEORGE CLINTON ANDREWS, Tarrytown, N. Y., to Miss Ina Washington Rigsby, Army Nurse Corps, December 17.

FRANCIS R. ANTHONY, Maryville, Mo., to Miss Cora M. Price of Fort Smith, Ark., December 24.

IVAN PETROFF BALABANOFF, Tacoma, Wash., to Miss Edith Weller of Winona, Minn., January 1.

LUCIA KEMP, Bucyrus, Ohio, to Mr. L. C. Feighner, December 31.

The Propaganda for Reform

IN THIS DEPARTMENT APPEAR REPORTS OF THE COUNCIL ON PHARMACY AND CHEMISTRY AND OF THE ASSOCIATION LABORATORY, TOGETHER WITH OTHER MATTER TENDING TO AID INTELLIGENT PRESCRIBING AND TO OPPOSE MEDICAL FRAUD ON THE PUBLIC AND ON THE PROFESSION

MISBRANDED NOSTRUMS

How the Bureau of Chemistry Is Protecting the Public Against Fraudulent or Misleadingly Advertised "Patent Medicines"

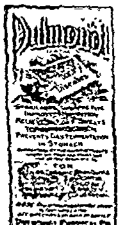
Royal Baby's Safety.—Shipped by Koloman Kovacs, trading as the Royal Mfg. Co., Dequesne, Pa. Analysis showed the product to contain, among other substances, approximately ⅛ grain morphin sulphate to each fluidounce, with alcohol, sugar, Rochelle salts and vegetable extractives, and indications of santonin. Falsely, fraudulently and misleadingly advertised. Fine, $50 and costs.—[*Notice of Judgment No. 5453.*]

Simpson's Cerebro-Spinal Nerve Compound.—Shipped by Chas. M. Simpson, trading as Dr. C. M. Simpson's Medical Institute, Cleveland, Ohio. Analysis showed the product to consist principally of alcohol, bromid, ammonium carbonate, and organic matter. Falsely and fraudulently advertised. Fine, $200 and costs. Defendant moved that the verdict and judgment be set aside and a new trial granted; motion overruled by the court. Defendant appealed case; Appellate Court affirmed the judgment of the lower court.—[*Notice of Judgment No. 5526.*]

Constitution Water.—Shipped by Stephen Demby, New York City. Analysis showed the product to consist essentially of a water-alcohol solution of iron acetate or chlorid, or both, glycerin, strychnin, and small amounts of alum and Epsom salt. Falsely and fraudulently advertised. Fine, $2.—[*Notice of Judgment No. 5530.*]

Tweed's Liniment.—Shipped by Wm. L. Davis, manager of Tweed Liniment Co., Chelsea, Mass. Analysis showed it was essentially a water-alcohol solution of chloroform, ammonia, turpentine, sassafras oil, and fixed oils. Falsely and fraudulently advertised. Fine, $10.—[*Notice of Judgment No. 5536.*]

Pulmonol.—Shipped by the Pulmonol Chemical Co., Brooklyn. Analysis showed the product to be essentially a glycerin-water solution of benzoate of soda, guaiacol sulphonate, and a little strychnin, colored with a coal-tar dye. Falsely and fraudulently advertised.[1] Fine, $25.—[*Notice of Judgment No. 5535.*]



Crown Skin Salve and Pile Cure.—Shipped by the Grace Medical Co., Des Moines, Iowa. Analysis showed the "Skin Salve" to be an ointment containing approximately 85 per cent. petrolatum, 7.6 per cent. mercuric oxid, 1.42 per cent. calomel, with indications of small quantities of camphor or menthol. Analysis of the "Pile Cure" showed it to consist of coco fat, tannic acid, atropin, alum, and talc. The "Salve" was falsely and misleadingly advertised, and the "Pile Cure" falsely and fraudulently advertised. Fine, $30 and costs.—[*Notice of Judgment No. 5591.*]

King of the World and Family Liniment.—Shipped by Gilbert L. Vrooman, Pierrepont Manor, N. Y. Analysis showed the product to contain over 84 per cent. of alcohol, 6.88 minims of tincture of opium to the ounce, with red pepper and safrol present. Falsely and fraudulently advertised. Fine, $2.—[*Notice of Judgment No. 5592.*]

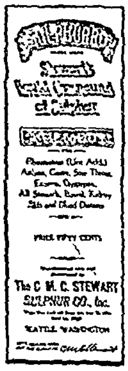
Ka-Ton-Ka.—Shipped by the Oregon Indian Medicine Co., Corry, Pa. Analysis showed the preparation to be essentially a mixture of alcohol, sugar, aloes and baking soda. Falsely and fraudulently advertised. Fine, $200 and costs.—[*Notice of Judgment No. 5537.*]

Greenhalgh Diphtheria Remedy.—Shipped by the Greenhalgh Remedy Co., Salt Lake City, Utah. Analysis showed it to be essentially a mixture of sulphur, borax, a trace of starch, plant tissue carrying berberin, iron, aluminum and potassium, as sulphates and nitrates, with charcoal and traces of manganese dioxid indicated. Falsely and fraudulently advertised. Fine, $100.—[*Notice of Judgment No. 5546.*]

Mountain Rose Tonic Tablets and Herbaline.—Shipped by the Springsteen Medicine Co., Cleveland. Analysis showed the "Tablets" to contain boric acid, tannin (or gallic acid), a zinc compound, unidentified alkaloidal material, vegetable extractive, sugar and acid-insoluble material, apparently talc. "Herbaline" was found to be essentially an ointment with a petrolatum base containing oil of eucalyptus, a thujone, containing oil such as tansy, and a small quantity of material insoluble in petroleum-ether but somewhat soluble in ether or chloroform. Both were falsely and fraudulently advertised. Fine, $100 and costs.—[*Notice of Judgment No. 5586.*]

Parmint.—Shipped by the International Laboratories, Binghamton, N. Y. Analyses of samples showed the stuff,[2] at various times, to contain from 9 to 15 per cent. of alcohol, about 3 per cent. volatile oil, from 14 to 33 grams of glycerin to each 100 c.c., and from 1 to 2 minims of chloroform to the ounce, also oil of peppermint, oil of turpentine, camphoraceous oil, and quinin. The product was colored with cochineal. Falsely and fraudulently advertised. Fine, $200.—[*Notice of Judgment No. 5593.*]

Sulphurro.—Shipped by the C. M. C. Stewart Sulphur Co. (Inc.), Seattle. Analysis showed the stuff[3] to contain about 4 grams of sulphur to each 100 c.c. and about 1½ grams of calcium to each 100 c.c. Falsely and fraudulently advertised. Fine, $150.—[*Notice of Judgment No. 5594.*]



"Liveon, The 90 Day Consumption Cure" and "Liveon Lung Discs."—Shipped by George H. Center, Du Quoin, Ill. Analysis showed the "90 Day Consumption Cure" to be a water solution containing sugar, plant material, emodin, tar and acetic acid. The "Lung Discs" contained essentially emodin, plant material, tar, starch and sugar. Both were falsely and fraudulently advertised. Fine, $50 and costs.—[*Notice of Judgment No. 5937.*]

White Beaver's Cough Cream and Wonder Worker.—Shipped by the Spence-McCord Drug Co., La Crosse, Wis. Analysis of the "Cough Cream" showed it to contain morphin, chloroform, creosote, ammonium chlorid, and methyl salicylate. Analysis of the "Wonder Worker" showed it to contain over 74 per cent. of alcohol, also chloroform, morphin, camphor, red pepper, oil of turpentine, and ammonia. Both were falsely and fraudulently advertised. Fine, $300.—[*Notice of Judgment No. 5599.*]

---

[1] This product, sold as a cure for consumption, was analyzed by the chemical laboratory of the American Medical Association in 1913, and exposed in the Propaganda Department of THE JOURNAL of the A. M. A., Nov. 29, 1913. The matter is reprinted in the pamphlet, "Consumption Cures," published by the American Medical Association, price 20c.

[2] This product was briefly discussed in the Propaganda department of THE JOURNAL, Aug. 18, 1917, p. 582.

[3] Sulphurro was examined in the A. M. A. Chemical Laboratory six years ago. The article appeared in THE JOURNAL, March 9, 1912, and is reprinted in "Nostrums and Quackery," 2d edition.

Watkins' Vegetable Anodyne Liniment, Female Remedy, and Kidney Tablets.—Shipped by the J. R. Watkins Medical Co., Winona, Minn. Analysis showed the "Anodyne Liniment" to be essentially a water-alcohol solution of oleoresin capsicum, camphor, oil of sassafras, and opium. The "Female Remedy" was found to contain over 19 per cent. of alcohol and unidentified extractive matter bearing emodin. The "Kidney Tablets" appeared to contain buchu, oil of juniper, pichi, magnesium, calcium, potassium and carbonates and nitrates. All were falsely and fraudulently advertised. Fine, $30.—[*Notice of Judgment No. 5605.*]

Nature's Creation Co.'s Discovery.—Shipped by the Nature's Creation Co., Columbus, Ohio. Analysis showed the product to be a water-alcohol solution containing inorganic material, apparently combined as magnesium sulphate and potassium iodid, with some emodin-bearing vegetable matter. Accompanying the solution was a tablet containing iron, sulphates, aloes, and licorice. Falsely and fraudulently advertised.[4] Fine, $100 and costs. —[*Notice of Judgment No. 5610.*]

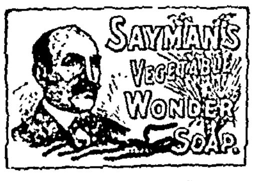
Radium Healing Balm.—Shipped by J. H. Frank Smokey, who traded as Uranium Mining Co., Denver. Analysis showed the stuff to be a soap with the odor of sassafras, and containing 9.3 per cent. of washing soda, 4.6 per cent. of baking soda, with 1.1 per cent. of sand, and 56.4 per cent of water. Falsely and fraudulently advertised. Fine, $10 and costs.—[*Notice of Judgment No. 5614.*]

Phuton Kidney Remedy.—Shipped by Mastin L. Williams, Arkansas City, Kan. Analysis showed the stuff to consist largely of water with about 3.5 per cent. alcohol and small quantities of plant extractive, ammonium chlorid, salicylic and tannic acids, and oils of sassafras and wintergreen. Falsely and fraudulently advertised. Fine, $5 and costs.—[*Notice of Judgment No. 5619.*]

Palmer's Skin Whitener.—Shipped by the Jacobs' Pharmacy Co., Atlanta, Ga. Falsely and fraudulently advertised. Ordered destroyed by the court.—[*Notice of Judgment No. 5598.*]

Byrnes Baby Relief.—Shipped by the Byrne Drug Co., Archbald, Pa. Falsely and fraudulently advertised. Product ordered destroyed; claimant to pay the cost of proceedings.—[*Notice of Judgment No. 5626.*]

Sayman's Healing Salve and Vegetable Wonder Soap.—Shipped by Thos. M. Sayman, St. Louis. Analysis showed the "Healing Salve" to contain chiefly petrolatum, zinc, boric acid, and camphor, with traces of a tarry oil. Analysis of the "Vegetable Wonder Soap" showed it to be a cold-process cocoanut oil soap. Both products falsely and fraudulently advertised. Fine, $40 and costs.—[*Notice of Judgment No. 5560.*]



Humphreys' Pile Ointment Witch Hazel Oil (Compound).—Shipped by Humphreys' Homeopathic Medicine Co., New York City. Analysis showed the preparation to be essentially a camphor ointment on a lard base. Falsely and fraudulently advertised. Fine, $25.—[*Notice of Judgment No. 5635.*]

Hill's Honey and Tar Compound.—Shipped by Laurence E. Cash, who traded as the New York Drug Concern, New York City. Analysis showed the product to consist essentially of water, alcohol (7.9 per cent.), sugars (56 per cent.), menthol, thymol, and a small amount of a substance similar to oil of tar. Falsely and fraudulently advertised. Fine, $25.—[*Notice of Judgment No. 5701.*]

"La Franco Combination Treatment" and "La Franco Vitalizer No. 200."—Shipped by Charles E. Luburg, who traded as La Franco Medical Co., Philadelphia. "La Franco Combination Treatment" included "Female Pills No. 2," "Blood and Emmenagogue Remedy," "Antiseptic Douche Powder," and "Tea Tablets." Analysis showed the "Female Pills No. 2" to consist essentially of aloes, emodin and green vitriol, with indications of ergotin and a trace of crude drug. The "Blood and Emmenagogue Remedy" was essentially iron, quinin, strychnin, and phosphate. The "Antiseptic Douche Powder" was essentially boric acid, borax, alum, carbolic acid and oil of peppermint. The "Tea Tablets" consisted essentially of milk sugar, oil of pennyroyal, iron and manganese oxids, and probably a small amount of caramel. The "Vitalizer No. 200" consisted essentially of iron, manganese, zinc, arsenic, phosphate, phosphid, and strychnin. All were falsely and fraudulently advertised. Fine, $75.—[*Notice of Judgment No. 5820.*]

Correspondence

"RULE AS TO PRIVILEGED COMMUNICATIONS APPLIED TO ROENTGENOLOGIST"

To the Editor:—In The Journal, Dec. 10, 1918, p. 2019, there is an abstract of a recent decision of the Idaho Supreme Court, wherein the law of privileged communications is applied to a roentgenologist, in a suit to recover damages for personal injury. This decision must have a far-reaching influence and should be brought to the notice of the entire medical profession. It points out that roentgenology should be applied only by licensed physicians, because the laws regarding privileged communications (where such laws exist) apply only to communications made to or information elicited by attorneys, clergymen or physicians. If the roentgen examinations, in the case cited, had been made by a layman, the supreme court would have reversed the decision of the trial court. In fact, the decision of the trial court would have been entirely different, in this particular phase of the case, if the roentgen examinations had been made by a layman. Besides the bearing this decision may have in the type of case cited, it might and could have a very important effect in a suit against a physician for malpractice, a subject well worth considering when roentgenologists or other specialists are brought into a case in consultation.

I. S. Trostler, M.D., Chicago.

"A REGISTRATION FEE FOR PHYSICIANS"

To the Editor:—In renewing my subscription, I wish to register my protest against the yearly registration of physicians with a fee of $2, as advocated by Mr. Shepardson (The Journal, Nov. 16, 1918, p. 1629). Three or four times that same article came to me, with increasing contempt and disgust on my part. Finally it found space in The Journal, and then came an editorial seemingly approving the scheme.

No doubt Mr. Shepardson believes that the medical profession would be much better under his immediate control, as he says that opposition will come from the more ignorant. I have no doubt that the kaiser thought the world would be better under his control, and the people were very ignorant for not seeing that. I am glad that I was one that was ready to sacrifice anything rather than bow to the kaiser, and I am glad to belong to that ignorant class from which Mr. Shepardson looks for opposition. Every physician and surgeon with whom I have talked belongs to the same class. Our county medical society has condemned the scheme. Some of these prominent men have a faculty for getting laws passed to suit them for which the benefit is not shown to every one. I remember with what contempt the man pushing the present birth registration law remarked that no physician would contend for a 25 cent fee on a paper on which he has spent two dollars' worth of work. Perhaps we would all despise a 25 cent fee if we held a state job; but now I find not only the fee gone but also the work; and expenses are greatly increased. For instead of sending in my birth reports to the county clerk at the end of the month, I have from six to twelve different men, any of whom may change office every year, to whom to make reports requiring at times telephone fees and extra postage. Is it any wonder that the officials are calling on their "registrars" for more complete reports?

---

[4] The "Nature's Creation" humbug was exposed by the Propaganda department of The Journal March 5, 1910, and further articles appeared Feb. 4, 1911, and March 30, 1912. The matter is reprinted in the pamphlet, "Consumption Cures," published by the American Medical Association, price 20 cents.

During the recent epidemic I was getting only about two hours' rest out of the day; but enough official notices and instructions came to keep a man busy two or three hours more. I protest against this registration as only another step in making the physician a dummy in the hands of the powers. I have no use for the quack; but must the entire profession be under guard on account of a few renegades? Incidentally, a two dollar fee is attached which over the entire state would amount to from $10,000 to $15,000. "To a man up a tree" it looks as if the moral to the whole thing is that some one needs a soft job riding over the country to see if the physicians are following the latest "goose step."

BLAIR KELLY, M.D., Ferris, Ill.

To the Editor:—The paper of Mr. Francis W. Shepardson (THE JOURNAL, Nov. 16, 1918, p. 1629) touches on matters of vital importance to every public spirited citizen as much as to physicians. While a lamentable state exists in the presence of charlatans in the community, the significance of this is not likely to be fully appreciated.

To go to the root of the matter requires a delicate discrimination, because criticism as usually made strikes as hard at the man as it does at his professional attainments. This sort of criticism is not only unjust but is useless. Medicine, in the last analysis, is what the country as a whole makes it. It is the barometer of progress. Going even farther: in communities the kind of medical service received depends largely on demand. If the demand is for a high degree of professional attainment, this demand is usually met. It follows as a corollary that highly cultivated communities have as a rule highly skilled medical advisers, and the contrary is true, that medical skill is apt to be of a low order in communities where this demand is absent. May it not be at times very difficult to differentiate, judging by results, the charlatan from the licensed practitioner? One recalls Osler's quip that the worst thing about quackery is that it sometimes cures. Sick humanity is not discriminating as to means; are we very sure that professional incapacity is not the chief asset of the charlatan?

An opportunity has fallen to me which has brought close professional contact with numerous physicians, from all states and of all degrees of education. The resultant impression of the average skill, knowledge and judgment of the practitioner is not a source of happiness to me. Man that he usually is, with a heart in the right place, too often he knows little or nothing about medicine. When, in examining general practitioners with a view of ascertaining capability to care for ordinary sickness, it becomes necessary to exclude questions on the signs differentiating mitral stenosis from aortic regurgitation, and pneumonia from pleural effusion because too many have found these difficulties insurmountable, it is bad; but when one finds general practitioners of alleged experience who have never given diphtheria antitoxin, have never seen it given, have never made exploratory puncture of the chest with a needle for fluid, have never done a lumbar puncture nor seen one done, then one becomes convinced that these practitioners have not recognized the clinical pictures they undoubtedly have seen. That such men are inefficient and a menace is not by any means always their own fault. They attended poor schools, supposing them good. Their internships were, perhaps, under inefficient men, and they were taught nothing.

[These statements, of course, will not apply to the physicians who have been or are being graduated under the greatly improved conditions now prevailing in all but a few of the medical schools. Frequently published classifications enable the student to make a wiser choice, and the higher entrance requirements, better laboratory and clinical facilities and greatly improved methods of teaching insure the turning out of physicians who have had a much better medical training than formerly.—ED.]

Experience avails little unless there is some mode of correcting mistakes. If we fail to recognize these deplorable conditions we shall fail also in providing means for a better state of things. It is not enough that students be taught sound principles in schools; equally necessary is it that they have served as interns in hospitals under competent masters. Medical skill is like music: it is acquired more by tradition, master to pupil, than from literature. From the community point of view, the eight states which require an internship in an *inspected* and *approved* hospital as a requisite have the only rational system of licensing.

Mr. Shepardson says we need organization. We do. We need first a clear statement of the object to be attained by organization. That object is not primarily any position of the profession of medicine. The primary object is public health. Each step toward success will bring to medicine honors sufficient. We know that much disease is preventable, yet as a body we hardly have made ourselves felt in putting into operation principles demonstrated and accepted. We have a federal health service, most states have health boards, and a few are subdivided into districts; but there is little or no interrelationship between these boards, and between the isolated practitioner and these several agencies no relation at all. Yet these are, in fact, the great servants of the state health officer. From these he should receive help on the one hand in preventing disease and on the other in caring for disease (sanitary inspections, state and district laboratories, hospitals and sanatoriums). If the isolated physician is not kept in touch with medical progress through these agencies, his lot is hopeless, for he has neither time nor money for postgraduate study away from home.

NELLIS B. FOSTER, M.D., Fort Oglethorpe, Ga.
Lieutenant-Colonel, M. C., U. S. Army.

Queries and Minor Notes

ANONYMOUS COMMUNICATIONS and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted, on request.

COCA-COLA

To the Editor:—Has "Coca-Cola" been analyzed? If so, I would especially like to know whether there is anything particularly injurious in it, and whether it is a habit-forming drink.

R. F. GRAHAM, M.D., Greeley, Colo.

ANSWER.—An analysis of Coca-Cola made by the federal chemists is published in a government bulletin known as Notice of Judgment No. 1455. This analysis declares the stuff to contain from 0.92 to 1.30 grains of caffein to the fluidounce. Various analyses have also been published in the advertising matter of the Coca-Cola Company. These all admit the presence of caffein in various amounts. It would seem that, in the interests of the public health, the indiscriminate sale to children and adults of an alkaloid like caffein in the enticing form of a "soft drink" should be deprecated. It is difficult to avoid the conclusion that the unrestricted use of Coca-Cola must be deleterious. It is probably true that a carefully graded dose of Coca-Cola contains no more caffein than the average cup of coffee, and if Coca-Cola as a drink were subject to the same limitations, so far as availability is concerned, there might be but little danger in its use. But people do not drink from five to fifteen, or twenty cups of coffee daily. That they do, in some cases, drink an amount of Coca-Cola equivalent in caffein content to that amount of coffee daily can, we believe, be substantiated. In THE JOURNAL, June 6, 1914, p. 1828, is published a communication from a Colorado physician describing a case of asthenopia in a caffein addict who was taking from three to six glasses of Coca-Cola daily in addition to two or three cups of strong coffee at mealtime.

Medical Education and State Boards of Registration

COMING EXAMINATIONS

Alaska: Juneau, March 4. Sec., Dr. L. P. Dawes, Juneau.
Connecticut: New Haven, March 11-12. Sec. Reg. Bd., Dr. Chas. A. Tuttle, 196 York St., New Haven; Sec. Eclectic Bd., Dr. J. E. Hair, 730 State St., Bridgeport, and Sec. Homeo. Bd., Dr. E. C. M. Hall, 82 Grand Ave., New Haven
Illinois: Chicago, March 3-5. Mr. F. C. Dodds, Supt. of Registration, Springfield.
Indiana: Indianapolis, Feb. 26-28. Sec., Dr. W. T. Gott, 84 State Capitol Bldg., Indianapolis.
Kansas: Topeka, Feb. 11. Sec., Dr. H. A. Dykes, Lebanon.
Massachusetts: Boston, March 11-13. Sec., Dr. W. P. Bowers, Rm. 501, No. 1 Beacon St., Boston.
Missouri: St. Louis, Jan. 28-30. Sec., Dr. G. H. Jones, State House, Jefferson City.
Nebraska: Lincoln, Feb. 12. Sec., Dr. H. J. Lehnhoff, 514 First Natl. Bank Bldg., Lincoln.
New Hampshire: Concord, March 13-14. Sec., Dr. Charles Duncan, Concord.
New York: Jan. 28-31. Albany, Buffalo, New York City and Syracuse. Mr. Herbert J. Hamilton, Asst. Prof. Exams., New York Dept. of Education, Albany.
Vermont: Burlington, Feb. 11. Sec., Dr. W. Scott Nay, Underhill.
Wyoming: Moorcroft, Feb. 12-14. Sec., Dr. H. E. McCollum, Laramie.

New York May and June Examinations

Mr. George M. Wiley, director, Examinations and Inspections Division, reports the written examinations held at Albany, Buffalo, New York and Syracuse, May 21-24 and June 25-28, 1918. The examinations covered 8 subjects and included 80 questions. An average of 75 per cent. was required to pass. Of the 276 candidates examined, 220 passed and 48, including 1 osteopath, failed, 8 of the candidates who failed at the May examination having passed at the June examination. The following colleges were represented:

PASSED

College	Year Grad.	No. Licensed
Howard University	(1917)	1

Arizona October Examination

Dr. Allen H. Williams, secretary of the Arizona Board of Medical Examiners, reports the oral and written examination held at Phoenix, Oct. 2-3, 1918. The examination covered 10 subjects and included 100 questions. An average of 75 per cent. was required to pass. Of the 15 candidates examined, 10 passed and 5 failed. The following colleges were represented:

PASSED

College	Year Grad.	Per Cent.
Georgia College of Eclectic Medicine and Surgery	(1916)	75.2
University of Michigan Medical School	(1908)	86.5
Barnes Medical College	(1893)	88

Medical College of Ohio	(1876)	1

Oklahoma October Examination

Dr. J. J. Williams, secretary of the Oklahoma State Board of Medical Examiners, reports the written examination held at Oklahoma City, Oct. 8-9, 1918. The examination covered 10 subjects and included 100 questions. An average of 70 per cent. was required to pass. Two candidates, 1 an osteopath, were examined, both of whom passed. Six candidates, including 1 osteopath, were licensed through reciprocity. Three candidates were granted reregistration licenses. The following colleges were represented:

PASSED

College	Year Grad.	Per Cent.
Baylor University	(1917)	71

LICENSED THROUGH RECIPROCITY

College	Year Grad.	Reciprocity with
Atlanta College of Physicians and Surgeons	(1909)	Texas

Book Notices

The Beginning of Science, Biologically and Psychologically Considered. By Edward J. Menge, M.A., Ph.D., M.Sc., Professor of Biology in the University of Dallas. Cloth. Price, $2 net. Pp. 256. Boston: Richard G. Badger, 1918.

In this booklet the author endeavors to explain the relationship between philosophy and laboratory science. Six of the chapters have appeared in the University of Dallas quarterly bulletins. The discussions are so advanced that they will appeal only to adults, or at least to those beyond high school age. As a whole, the book forms a brief review of the present status of biology and scientific philosophy. The author is careful to present both sides of the subjects he discusses. His chapter on theories of evolution is an excellent presentation of the developments in this field.

Surgery at a Casualty Clearing Station. By Cuthbert Wallace, C. M. G., F.R.C.S., Surgeon. St. Thomas' Hospital, and John Fraser, M. C., F.R.C.S.E., Assistant Surgeon, Sick Children's Hospital, Edinburgh. Cloth. Price, 10 shillings, 6 pence. Pp. 320, with 63 illustrations. London: A. & C. Black, Ltd., 1918.

The great war has developed a new terminology. Probably few readers of The Journal have a clear idea exactly what a British casualty clearing station is. The military hospital has evidently followed the same line of development in the British army as in the American. Prior to the South African war, the British military hospital equipment consisted of the field hospital and the base hospital. The field hospital was a mobile unit attached directly to the division, going forward with the troops in the field, planned and equipped so as to be capable of quick erection and demolition, and of as rapid movement as the exigencies of the military situation might require. To it were brought the wounded from the regimental aid station and the ambulance dressing station, either on foot or in ambulance or by the litter squad of the ambulance company. The field hospital contains no cots, beds for the wounded being made with blankets on top of straw, hay or leaves, or lacking these, rubber blankets on the ground. Only the imperatively necessary operations of emergency are done. Dressings are changed and adjusted, hemorrhages checked, splints applied, nourishment and stimulants administered and, as rapidly as possible, the wounded are evacuated toward the rear and the field hospital emptied and prepared for another influx of patients. When the zone of the advance is near the base of supplies, patients from the field hospital can be evacuated directly into the base hospital, which is a practically immobile unit; but when, as in Africa, and later on in France, the line of communication involves from 100 to 150 miles of rail and from 10 to 20 miles of motor transportation, the gap between the field hospital and the base hospital is too wide for practical purposes. Hence the evolution during the Boer war with the British, and during the Mexican border activities in our army, of what is known in this country as the evacuation hospital and in England as the casualty clearing station—an intermediate unit less mobile than the field hospital and more mobile than the base hospital; situated generally at the rail-head, receiving the evacuated wounded from two to half a dozen field hospitals; more completely equipped and capable of rendering more extended service than the field hospital, yet continually evacuating to the base hospital by hospital trains the sick and wounded whose condition is too serious to permit of their being returned to active duty in a short period. When the interval between the rail-head and the front lines is too small to make a field hospital necessary, the evacuation hospital becomes the first link in the system, and receives the wounded direct by ambulance from the advanced dressing stations. So recent has been the development of this military medical unit that comparatively no literature on the subject was in existence prior to the European war. This book embodies the results of several years' experience on the western front, and comprises the observations and methods of a large number of army surgeons. Chapters on organization, shock, general treatment, antiseptics, injuries of bones and joints, abdominal and chest wounds, injuries to the head, spine and nerves, hemorrhages, gas gangrene, amputations, transfusions, injuries to the eyes, and tetanus cover practically all the essential features of the work of the casualty clearing stations. The book is copiously illustrated with drawings and diagrams, mostly of recently devised apparatus and instruments. Being made up practically of new material, it has a freshness and interest not generally found in surgical textbooks. The military surgeon will be interested in the experiences of his professional brother on the western front, while the surgeon in civilian practice can get many valuable hints as to methods, the improving and devising of apparatus, etc.

Social Medicine, Medical Economics and Miscellany

The Black Demon, or Exorcising Smallpox

In a publication of the American Baptist Foreign Mission Society, Dr. Charles R. Manley, of the Clough Memorial Hospital, Ongole, South India, describes graphically the ceremonial of the natives of a community in driving out an epidemic of black smallpox. It should make good reading for the antivaccinationists. Dr. Manley's story is as follows:

The tom-toms beat all night and this morning the streets are fairly covered with chicken feathers. For black smallpox has taken the city and must be driven out. The priests have told the people to kill chickens and strew their feathers in the streets so they will catch the eye of Polerimah, the plague demon, and distracts her attention. The tom-toms throbbing in the air will either frighten her or please her so much that she will forget to jump down the throats of any careless mortals whom she might find with mouths opened in speaking, or with lips parted, or sleeping with uncovered faces. Yes! the goddess Polerimah is angry with the people.

Yesterday afternoon they made a big *tamasha*, or feast, in her honor. A few of us foreigners heard that it was to take place and went down to the bazaar to see what we could see.

In the very heart of the bazaar, our native servants told us, we should find Polerimah in all her glory. We wedged our way through the masses of men and women who filled the place and found ourselves at last before the little hut of green reeds that had been erected over the goddess. I must confess I was surprised and disappointed at what I saw when I peeped in. After all the fuss they had made and the huge pile of rice they had heaped up as an offering, I expected to see at least a life-sized lady demon. But instead I saw only a squat little figure, no more than a foot tall, made of black mud and covered with tinsel. She was soaked with lemon-colored water which dripped off her shoulders into a widely spreading puddle round her feet.

"Why so much wetness?" I asked with an amused smile.

"They must keep her cool," answered our guide with great dignity. "If she gets warm she gets mad. So they have built this temple of reeds to protect her from the sun, and every few minutes the priests pour saffron tinted water over her. Whatever happens she must be kept cool."

. . . .

In front of the "wickie-up" was a constantly increasing pile of cooked rice awaiting its sprinkling of life-blood to make it a food fit to satisfy the ravenous and blood-thirsty appetite of the goddess. Just beyond the rice-pile we could see a priest sitting on the ground bending over a smudge pot of burning incense. At that moment he turned to look at us and the terrible shape of his countenance made us cringe. His eyes were blood red and swollen and his sensuous mouth hung open. He was waiting for the demon to leap through the smoke and down his throat.

"Then," said our guide, "when he is demon-possessed, he will speak, and whatever he says the people will do it."

. . . .

We watched for a while the delegations of men and women coming from different parts of the town, bringing their offerings to Polerimah. With the blare of horns, the throb of tom-toms, the cries of the frantic wild-eyed dancers, band after band came in unvarying march around the little hut-temple, presenting their offerings and augmenting the rice pile. The priests meanwhile fought among themselves for the various titbits and dainties that the more zealous women had brought with their rice. The scene began to take on the aspects of a dog-fight as the priests, getting more excited, snarled and snatched delectable morsels from the women and even from one another. Hearing a commotion behind us we turned to see a band of priests coming up on the run, leading a buffalo bull. He was dyed with saffron, a wonderful canary yellow, and hung with garlands and with flowers. Behind him came a huge, savage black-faced fellow, holding aloft a great sickle-shaped knife in a hand that was white as snow.

"The bull is another offering," muttered my guide in my ear. "The big priest with the white hand must strike off his head with a single blow of the knife, and then the blood must be sprinkled all over the sacred rice pile before the goddess will accept her feast."

. . . .

By this time the sun had slid pretty well down toward the horizon, and it was evident that something more was about to happen. A sudden yell was followed by a mad surging of the crowd toward the temple, which they tore to pieces in almost less time than it takes to tell it. In another instant every one was waving a reed in the air.

"Now what will they do?" we asked.

"They are arranging to escort the goddess out of the town," said our guide. "They have done everything they could to appease her anger and make her happy; and now they are going to carry her out of town while she is still in a happy frame of mind, and throw her in the ocean."

The procession was formed. First came the priest carrying on his head a basket in which were the bull's entrails, crowned by his head, holding in his hideous, grinning mouth the bone of his front fore-leg. Behind him came the goddess, carried on the head of another priest. And as the throng proceeded down the street, people by the wayside wrung the necks of chickens and threw the headless bloody bodies over the people's heads toward the image. The horns blew, the tom-toms throbbed and the people yelled themselves hoarse, waving their reeds in the air. What is the priest screaming?

"Yell, brother, yell. Let confusion reign! Let not the terrible Polerimah suspect our fell designs, and fall upon us before we are safely rid of her!"

Following in the wake of the procession, I came up to a young mother who was hurrying along dragging a tiny child by the hand. The little girl was staggering, her bare body was a mass of scars, her eyes heavy and dull with the intoxication of the dread disease. The child mother cried out to Polerimah to have mercy. As her wails mingled with the shrieks of thousands the procession passed down the crooked, dusty road and out of sight.

Tonight, out there in the dark somewhere, many young mothers are sitting in black despair, because in spite of all their sacrifices to the demon, the lives of their babies stricken with the fearful plague are surely ebbing away.

Dried Milk as a Food for Infants

A report of great importance has been made to the Local Government Board by Dr. F. J. H. Coutts on dried milks with special reference to their use in infant feeding and issued as a government publication. Dr. Coutts says that the experience of the last twelve or fourteen years shows that dried milk is one of the most satisfactory forms of cow's milk for the feeding of infants. It has been largely employed in connection with infant welfare centers, particularly in Leicester and in Sheffield. A large proportion of babies take and digest dried milk very well; they thrive on it and develop well. Vomiting is less frequent with dried milk than with ordinary cow's milk. Fresh, clean, pure, raw cow's milk is a very good food for a baby when mother's milk is not available, but unfortunately the milk ordinarily sold in towns is often far from clean and contains large numbers of germs. Such milk, especially in summer, will not keep a day without becoming sour, and is apt to cause digestive troubles. Dried milk contains far fewer germs than ordinary town milk, and is less likely to contain the germs of infectious diseases. Also germs do not multiply in dried milk as they do in ordinary milk. Dried milk keeps well so long as it is kept dry. Only as much should be made up at a time as is required for one feed, and there need, therefore, be no waste. Pasteurized, sterilized or boiled cow's milk are useful foods if properly prepared, but they have disadvantages as compared with dried milk. Unsweetened full cream condensed milk is also useful for baby feeding, but when mixed with water in the proportions sometimes recommended it is too weak for satisfactory nourishment. Sweetened condensed milk is often used for baby feeding. Dried milk has the advantage, when made up with the proper proportion of water, of containing the essential food elements in a proportion more suitable than full cream sweetened condensed milk. The latter, if made up so as to give the right proportion of fat, has a very excessive amount of sugar. The baby usually becomes fat and flabby, and is liable to suffer from diseases, such as rickets. These risks attach to other infant foods containing excess of sugar. So-called "malted" milks, like sweetened condensed milks, contain much too low a proportion of fat as compared with sugar. They differ from sweetened condensed milk in the nature of the sugar. In condensed milk this is mainly sucrose; in malted milk it is largely maltose derived from the malted cereal. The ordinary patent infants' foods, containing large quantities of unaltered starch, are worse than sweetened condensed milk or malted milk. They are not fit for use for a baby under 7 months.

It is not surprising, therefore, that at official infant welfare clinics dried milk is becoming used to an increasing extent as, on the whole, the most convenient and most suitable food when babies cannot get breast milk. In feeding babies on dried milk, the full cream variety should alone be used. Commencing with 1 teaspoonful of dried milk in 3 tablespoonfuls of water in the first or second weeks of life, it can be rapidly increased to 1½ or 2 teaspoonfuls of dried milk in from 4 to 5 tablespoonfuls of water by the end of the second month, and so on to 5 teaspoonfuls of dried milk in 10 tablespoonfuls of water at the age of 5 or 6 months. Fears were at one time expressed that the use of dried milk might result in scurvy or rickets. Prolonged experience at infant welfare centers has refuted this; but as an extra precaution to avoid the possibility of scurvy, particularly if dried milk is to be used for a long time, a little fruit juice, such as orange or grape juice, may be given once or twice a week. Dried milk is also a valuable food for nursing mothers. In a very large number of towns dried milk for baby feeding is supplied from infant welfare centers, at which advice is also given as to the method of preparing and using the food.

Massage Versus Gymnastics in Rehabilitating the Crippled

Hitherto chief reliance has been placed on massage to set free stiff joints and limbs—a most valuable and helpful agent when rightly applied. Devoted women have given themselves up to the carrying on of this work, and most admirable results have often been obtained; but with every desire to appreciate their work, and with no desire to belittle its value, one has had forced on one's mind sundry factors that indicate limitations in its utility. The ordinary medical man who orders massage for a patient knows nothing from personal experience of the methods employed, or of the results obtained or obtainable. He hands the patient over to the "massage department" with smug satisfaction that he has done his duty in an up-to-date fashion, and troubles no more about the matter. The massage is carried out, as a rule, by a woman who knows nothing but massage and perhaps a little electricity, and her horizon being thus limited, she will continue massaging a case most assiduously and devotedly when all hopes of gaining improvement thereby have long ceased. Often one has seen hopelessly ankylosed joints being rubbed to regain movement, and limbs with divided and unsutured nerves being similarly treated. It is pathetic to see a little but devoted masseuse struggling with a strong man's stiff shoulder held by powerful muscles; to get the patient's weight to act on the arm would do more toward regaining movement in five minutes than five months of massage. To get good results the patient's own will must be brought into action. There are no particular inducements for the fighting man to get well more quickly than he can help; the allurements and comforts of the trenches are not such as to urge him to rapid convalescence, and he is quite ready to go on being rubbed or having passive movements of limbs at the hands of a masseuse, or in the grasp of a machine, as long as may be without himself putting out an ounce of effort to hasten the cure.—Col. A. Carless, Preface to Gymnastic Treatment for Joint and Muscle Disabilities.

Medicolegal

"Clairvoyant Doctor" an Illegal Practitioner

(People v. Kenyon (Mich.), 167 N. W. R. 997)

The Supreme Court of Michigan says that in this case, wherein the jury returned a verdict of guilty on a charge against the defendant of practicing medicine without a license, and which case was before the supreme court on exceptions before sentence, the court was unable to find error in the record which would warrant a reversal of the case, and therefore affirmed the conviction and directed the trial court to proceed to judgment. The prosecution showed that the defendant was not registered in Eaton, Calhoun or Barry counties as a physician, and also introduced the testimony of a number of witnesses to the effect that he had not merely furnished medicine, but had given treatments to a number of people in Battle Creek and elsewhere, the treatments consisting principally in rubbing on some sort of salve or oil, and occasionally giving a powder to take internally. Before giving a treatment he would "go into a trance," as the witnesses expressed it, claiming to be under the guidance and control of an Indian spirit, who would talk to him and tell him whether or not he could cure the patient and also what to do to effect the cure. In a number of instances it was shown that he stated positively that he could cure the patients. Those witnesses stated that they had gone to him for medicine or treatment because they had heard him spoken of highly by others whom he had treated; that they had seen no advertisement nor anything with the title "Doctor" used in connection with his name, though they were in the habit of calling him "Dr. Kenyon." During the cross-examination of the defendant, he identified a number of letters written by his wife for him during the years 1913 and 1914 to a Miss Carrie Holmes, which were signed "Dr. Levi Kenyon," the envelops of which bore the return card, "Dr. Levi Kenyon, Bellevue, Mich.," which letters were received in evidence, as was also a printed card which he identified, reading as follows:

> Clairvoyant Doctor. I diagnose Cases Anywhere in the United States free of Charge.
> Bell Phone 50 3-4
> R. F. D. No. 4
> Dr. Levi Kenyon,
> Bellevue, Michigan.

The defendant endeavored to show that during the period set forth in the information (July 1, 1915, to Dec. 8, 1916) he did not practice medicine and did not hold himself out at all to cure or alleviate human ailments, but simply sold herbs, roots and ointments prepared by himself which might, if used, be of benefit to afflicted human beings; that during the period in question he did not advertise or hold himself out to cure diseases, or in any way violate the section of the statute in question.

The supreme court holds that there was no error in permitting the information to stand without the exceptions of the statute concerning osteopaths, etc., being mentioned, the rule being well established in Michigan that in declaring on a statute where there is an exception in the enacting clause the pleader must negative the exception, but where there is no exception in the enacting clause, but an exemption in the proviso to the enacting clause or in a subsequent section of the act, it is a matter of defense, and must be shown by the defendant. The court also holds that, the defendant having testified, on direct examination, that he had never held himself out as being a physician or a surgeon, it was not error to allow cross-examination of the defendant and the introduction thereon of exhibits mentioned, the introduction of the letters as being on his credibility. Furthermore, in view of the statement made by the defendant while on the stand in his direct examination that he had never diagnosed a case of any person coming to him, and that he had never made a fixed charge for his remedies, the court does not think error was committed in allowing the witness Carrie Holmes to relate as part of the direct case circumstances that occurred at the time the letters to her were written.

Things Wanting to Sustain Action for Fees

(Paine v. Eckhardt et al. (Texas), 203 S. W. R. 459)

The Court of Civil Appeals of Texas reverses a judgment for $500 obtained by the plaintiffs in this action for debt brought by two practicing physicians, because the contention of defendant Paine must be sustained, that the judgment was contrary to and unauthorized by law, in that both the pleadings and the evidence failed to show that the plaintiffs, or either of them, had complied with the requirements of law, and especially with the provisions of Article 5736 of Vernon's Sayles' Civil Statutes, in that the pleadings failed to allege, and the evidence to show, that the plaintiffs, or either of them, had complied with the statute regulating the practice of medicine. The court holds that it was also fatal to the plaintiffs in this case that the pleadings and the evidence did not show any copartnership or other interest of the plaintiffs in the right to compensation of the other by which they could maintain or recover on a joint cause of action.

Color Blindness Not Loss of Sight

(Kane v. Brotherhood of Railroad Trainmen (Neb.), 168 N. W. R. 598.
Routt v. Brotherhood of Railroad Trainmen (Neb.),
168 N. W. R. 599)

The Supreme Court of Nebraska reverses in these two cases judgments obtained by the plaintiffs on account of color blindness as for a complete and permanent loss of sight. Moreover, for reasons stated in the Kane case, the court, in the Routt case, considered on a rehearing, overrules its former decision holding color blindness to be such loss of sight (101 Neb. 763, 165 N. W. R. 141).

The court now holds, as stated in the Kane case, that one who is color blind, but whose vision in other respects is unimpaired, has not suffered "complete and permanent loss of sight of both eyes." The fact that the plaintiff was a railroad trainman, and on account of color blindness was discharged from his employment, did not entitle him to recover the amount payable under a provision of a benefit certificate that a member of the organization in good standing, "who shall suffer the complete and permanent loss of sight of both eyes, . . . shall be considered totally and permanently disabled"; there being no provision that the term "totally disabled" should mean "totally disabled" from following railroad work.

The court says that the constitution of the defendant provided that a beneficiary member of the class to which the plaintiff belonged in good standing "who shall suffer the complete and permanent loss of sight of both eyes . . . shall be considered totally and permanently disabled, but not otherwise, and shall thereby be entitled to receive, on furnishing sufficient and satisfactory proofs of such total and permanent disability, the full amount of his beneficiary certificate." The majority opinion in the Routt case held, in substance, that the language of the contract was ambiguous, and that a member of the association who was unable longer to continue in train service, and was discharged therefrom, on account of color blindness, had suffered a complete and permanent loss of sight of both eyes, within the meaning of the contract. But the defendant, by its constitution, insured only against death and against certain specified disabilities. It made no provision to insure against the multitude of other classes of injuries which a member might sustain, and which might equally incapacitate him from carrying on his work, and was therefore not avocational insurance.

The evidence showed that the plaintiff's sight was perfect except that he was unable to distinguish certain colors. In the ordinary use and meaning of language, when one has suffered the complete and permanent loss of sight of both eyes, he is totally blind. It is true that ambiguous expressions in an insurance contract should be construed most strongly against the insurer, because it writes the contract; but where there is no ambiguity, and the plainest and clearest of ordinary language is used, courts are not warranted in striving to give distorted and unusual meanings to words in order to reach what is believed to be a benevolent result. Furthermore, the defendant's constitution specified that its provisions should be "interpreted and construed according to their most plain and obvious meaning." In order to bring the plaintiff within the insured class there must be a complete perversion of the usual and ordinary meaning of the language employed.

Society Proceedings

WESTERN SURGICAL ASSOCIATION

Twenty-Eighth Annual Meeting, held in Chicago, Dec. 20 and 21, 1918

The President, Dr. James F. Percy, Galesburg, Ill., in the Chair

Our Duty to the Industrial Army

Dr. R. W. Corwin, Pueblo, Colo.: Our duty as surgeons to the industrial army may be considered under two heads: (1) treatment after injury, and (2) treatment before injury—surgical prophylaxis. What are some of the prophylactic duties of the surgeon? In a broad sense to educate the employee: obtain the endorsement of the employer; urge national and state cooperation; make known the laws of eugenics, and insist that the breeding of man is as important as the breeding of cattle. Specifically, we should teach first aid, surgical hygiene and sanitation. We should teach the nature of wounds, the process of wound healing and of wound poisoning, the importance of early attention, and the relation of health to wounds. We should teach the relation of venereal diseases to wounds, and the importance of not bandaging tightly, of the care of the feet, of properly fitted shoes, and of position in lifting so as to prevent sacro-iliac injuries. The industrial army demands surgical protection as well as surgical treatment. Are we *not to protect* as well as save? Is not the surgeon best qualified to satisfy this demand? Has not the surgeon been too modest and permitted others to occupy his territory? Is it not time for the surgeon to assert his rights? Is not his duty to the industrial army plain? Now that peace is here, let us become instructors, not for war but for work.

DISCUSSION

Dr. D. S. Fairchild, Sr., Clinton, Iowa: I have examined about 16,000 men for army service and 5,000 for railroad service, and my conclusions are that we need to inquire first into the ways of living. If every industry could establish a plan of examining the men received into service and then ascertain how these men live, we would have something to go on in judging how to improve conditions. In our state 20 per cent. of the men rejected because of physical disability were under 30, and over that age more than 30 per cent. were rejected, or about the same as the men for railroad service. It was thought that on account of war conditions it might be necessary for our railroad people to employ men who would not be accepted under ordinary conditions, and I took the opportunity of visiting the homes where many of these men lived, the older men who would not be taken under ordinary conditions. I found the homes filthy and vice prevailing to a large extent. If we could start out with a plan of physical examination and follow this up by finding out how these people live, we should know what we must do in order to improve conditions.

Dr. John P. Lord, Omaha: We all realize the great amount of physical disability that has prevented men from being accepted in the military service, and these men are very anxious to have that physical disability removed in order that they might enter the service. The physical requirements are made in the various branches of the military service, and this has intensified the interest of people in their own physical conditions and they have tried to remedy them. Nurses ambitious to enter the nursing service would seek to have foot defects relieved so that they could get into service. If large corporations exact these things, and many of them do, the individuals are going to see to it that they are made fit for their jobs.

Dr. George N. Kreider, Springfield, Ill.: I have examined 800 medical men and have been very much surprised to find a large *proportion* handicapped and unable to get into the service on account of overweight. When I told them that it was possible to lose that weight and fit themselves for the service, at least 70 per cent. undertook to do it. Bad shoes are responsible for gastroptosis, heart trouble and many other conditions, and it is important for a surgeon to bear this in mind and lend his assistance to every effort to get better shoes.

Surgical Treatment of Exophthalmic and Thyreotoxic Goiter, with Special Reference to Bilateral Resection

Dr. Neil John Maclean, Winnipeg, Manitoba, Canada: The advantages of bilateral resection over unilateral lobectomy with partial lobectomy of the opposite lobe are: 1. There is a *minimum* of injury to the parathyroids. 2. There is absolute safety for the recurrent laryngeal nerve. 3. If for any reason further removal of the gland should be indicated, the one side could be removed completely with an assurance that some portion of gland remained. 4. Compensatory hypertrophy does not occur after double resection. 5. For cosmetic purposes, in the operation of lobectomy there is a well marked depression on the side from which the lobe has been removed, and on the other side the portion of gland left produces an undue prominence, while in bilateral resection the neck is symmetrical.

Purgation Before and After Abdominal Section

Dr. Henry T. Byford, Chicago: This paper will be published in full in The Journal.

DISCUSSION

Dr. Howard Hill, Kansas City, Mo.: No cathartic is necessary immediately before operation. Many people are chronically constipated and they should receive the proper treatment, but not just before operation. Generally speaking, a person whose bowels have been moving normally up to the time of operation does not need a cathartic at that time.

Dr. C. H. Wallace, St. Joseph, Mo.: I have not been giving cathartics before operation for several years, as my experience teaches me that it is rather harmful. If a patient comes with a history of regular bowel movements every day, he is not given a purgative but an enema the next morning. These patients suffer much less from postoperative vomiting than when purgatives are given before operation.

Dr. A. J. Ochsner, Chicago: I have made a practical study of the use of purgatives before operations for the last thirty-two years. I have tried all of them, from calomel to castor oil, and have come to the conclusion that the principle laid down by the essayist is the correct one. If you give cathartics, you must not give anything that will fill up the intestine again before the operation.

Dr. James F. Percy, Galesburg, Ill.: Some men give an enema about 4 o'clock in the morning, so that the lower bowel is cleaned out at that time. It is not a very agreeable experience.

Empyema

Dr. Emil G. Beck, Chicago: Stereoroentgenograms will corroborate the diagnosis of empyema very early. Aside from operation, repeated puncture and withdrawal of small quantities of fluid may cure empyema. Operation should not be performed in the very acute stages when the fluid is still serous. A few ounces of the fluid may be removed by puncture to relieve distressing symptoms; drainage is to be reserved when the secretion is distinctly purulent, and will furnish about 50 per cent. sediment in twenty-four hours.

Introduction of a catheter through a cannula at the lowest level posteriorly is most desirable. Withdrawal of 2 or 3 ounces daily allowing any air to enter the cavity is the best treatment. I advocate counterdrainage in the lowest part of the cavity anteriorly, passing a catheter through both openings. If resection of a rib is done, it should be the eighth or ninth rib posteriorly. This affords best drainage for the patient sitting, standing or lying down. Local anesthesia is advocated in all cases.

Irrigation with Carrel-Dakin solution is advised for the first few days to dissolve fibrinous adhesions. Further irrigation is discontinued if possible, and spontaneous dry drainage is allowed to follow. Injections of bismuth paste will close from 80 to 90 per cent. of the cases if employed properly. A mixture of oil and bismuth is dangerous because the bismuth subnitrate will settle in the most dependent cervices in a few hours from which it may be difficult to remove, and thus cause bismuth poisoning. The bismuth in a petrolatum mixture will precipitate and thus will not be dangerous.

For the chronic suppurative cases, with sinus or lung abscess or empyema, which have persisted in spite of treatment, the skin sliding flap operation is reserved. It is much easier and less dangerous and more effective than the Estländer and similar procedures.

Surgical Complications in One Thousand and Thirty Cases of Influenza

Dr. C. J. Rowan, Iowa City: These cases occurred in the student body of the University of Iowa during October, 1918. Barrack life of the Students' Army Training Corps was responsible for so many cases among a student population of slightly over 3,000, and permitted an early and close observation of the cases. Empyema was the most important surgical complication. It occurred only in the pneumonia cases, of which there were about 100, and was the cause of death in each of thirty-three fatal cases. Appendicitis was not a common complication. Many patients had the gastrointestinal form of influenza, and in quite a number of these there was finally pain, tenderness, and rigidity localized in the right lower quadrant. This was marked enough in some cases to lead to the diagnosis of acute appendicitis and to have indicated operation in ordinary times; but I felt that it was extremely important to avoid unnecessary operations in these influenza patients, that the involvement of the appendix was only a part of the enteritis of influenza; that recovery would take place unless secondary infection of the appendix occurred, and that secondary infection would be shown by the development of leukocytosis. Two of the patients did develop leukocytosis, and appendectomy was done at once in each case under gas and oxygen anesthesia. Whatever the primary cause of the influenza may be, the bacteria mostly concerned in the complications are pneumococci and streptococci.

Carcinoma of Small Intestine

Dr. E. S. Judd, Rochester, Minn.: In reviewing our records I found five cases of primary carcinoma of the duodenum. In one of these cases a gastro-enterostomy was done for an inoperable obstruction and relieved the patient for a time. At necropsy, several months later, pathologists reported carcinoma of the duodenum extending up to the pylorus. In the second case there was a carcinoma of the pyloric end of the stomach, and beginning just above the pylorus, independent of the pyloric tumor, was a malignant papilloma of considerable size. In the third case, the original tumor was presumably of the first portion of the duodenum, although the ampulla was obliterated, and from the extent of the trouble it was difficult to determine at what point it originated. The fourth case was quite similar to the third, and was an extensive malignancy. The fifth case was a large carcinoma originating in the first portion of the duodenum.

I have collected twenty-four instances from the records of the Mayo Clinic. During the same period there were 1,689 cases of carcinoma of the stomach, and 1,822 cases of carcinoma of the large intestine. We have had eleven cases of carcinoma of the jejunum, six cases of carcinoma of the ileum, and two cases of multiple carcinoma of the small intestine. One of these patients died from pulmonary embolism following operation, and the other died following operation. At the necropsy there was revealed a papillary cystadenoma of the jejunum, which was removed at operation, a papillary cystadenoma of the duodenum, cirrhosis of the liver, cholangeitis and chronic cholecystitis of the strawberry type with papilloma.

DISCUSSION

Dr. Arthur Dean Bevan, Chicago: We have had no case of primary carcinoma of the duodenum in which we have recognized the condition as such and operated. We have, however, had a number of cases of primary carcinoma of the small intestine, that is, in the upper jejunum. Carcinoma of the small intestine gives much the same picture as a pyloric obstruction, but some points are very different, such as the vomiting of a large amount of material that has accumulated in the stomach and entire jejunal loop, and attacks of partial obstruction resembling greatly the partial obstructions in the large intestine, which have been temporary but fairly acute. The diagnosis can be made with much more certainty by means of the roentgen ray than any other way.

As to therapy, we have given up the idea of making an end-to-end anastomosis in these cases. A lateral anastomosis is three or four times safer for the patient in these cases of carcinoma of the small bowel. Carcinoma of the small intestine, when early diagnosed, gives a favorable prognosis. We have three patients who have been well for a number of years after circular resection for carcinoma of the small intestine.

Are We Justified in Removing a Comparatively Healthy Gallbladder?

Dr. W. H. Magie, Duluth, Minn.: I am in favor of saving the gallbladder in at least a majority of the cases. I have never seen an empty or collapsed gallbladder. The fact that it is always filled with bile proves that it has much to do with keeping up and regulating the pressure in the bile ducts and liver. This theory is supported by the results of experiments on animals. When the gallbladder is removed in dogs, the remaining cystic duct dilates, as do the common and hepatic ducts. The dilatation of the cystic ducts takes on the appearance of Nature's making an effort to reproduce the gallbladder. This dilatation of the cystic duct has been observed in man after cholecystectomy. This effort of Nature to reproduce the gallbladder is evidence that the gallbladder not only has the function of storing bile, but also has a pressure regulation function on the biliary system. These facts should be taken into consideration when the question of cholecystectomy versus cholecystostomy is to be decided. I have seen the majority of patients with empyemic gallbladders get well and stay well after drainage. If such results can be obtained from empyemic gallbladders, we can expect a mildly diseased one to recover and become again a functionating organ.

Cholecystectomy has a much greater mortality than cholecystostomy. I have had no mortality in my cholecystostomies. Not more than 5 per cent. of patients have required reoperating, and in every case it was on account of overlooked stones or stricture of the cystic duct. Cholecystectomy should be resorted to in: (1) all cases of hydrops with stricture of the cystic duct; (2) many cases of acute gangrene or threatened gangrene of the gallbladder; (3) all cases complicated with embedded stones in the cystic duct with ulceration produced by contact with the embedded stone that when healed would probably cause stricture; (4) all very thick walled gallbladders due to fibrous or calcareous degeneration; (5) all cases of ulceration due to pressure of large stones, and (6) cancer of the gallbladder when the disease is limited to the gallbladder.

Factors That Determine the Relative Degree of Cure in Biliary Surgery

Dr. B. B. Davis, Omaha: The most frequent causes of lack of complete relief are: (1) impediments, as the result of strictures, torsions and lessened elasticity of the common or hepatic ducts to the free passages of the bile to the duodenum; (2) lack of elasticity and contractility of the gallbladder wall, resulting in stagnation of the bile in that viscus, and continuous infection, and a tendency for reinfections; (3) adhesions of the gallbladder to the pylorus, transverse colon, omentum and liver; (4) stricture or kink of the cystic duct. A large part of postoperative distress is due to gallbladder adhesions. The only effective way to avoid pericholecystic adhesions is to remove the gallbladder, and this is the most potent argument in favor of indiscriminate cholecystectomies. Surgeons have been compelled to resort to this measure because of the very unsatisfactory results following the more conservative operation. If any effective means could be found for preventing postoperative adhesions, most of the gallbladders now removed could be retained.

Diagnosis, Treatment and End-Results in Fracture of Skull

Dr. W. D. Haines, Cincinnati: Some of the most extensive and fatal brain and cord lesions have followed injury wherein no fracture was found in the ward, roentgen room or dead room. Skull fracture patients are almost without exception suffering from some degree of shock, ranging from slight depression to profound unconsciousness when admitted. Infinitely more good will be accomplished for the patient by employing measures to relieve shock than by immediate operation, the one exception being the presence of active hemorrhage, and even here there is room for argument. Linear fracture of the skull without displacement will require evidence other than that obtained by palpation in their recognition. In suspected cases wherein the roentgen ray is not available, exploration or lumbar puncture, preferably the latter, will aid in establishing the diagnosis. Percussion is of value in such instances, but evidence thus obtained should be confirmed. Shock and altered reflexes enter into the scheme of diagnosis and must be given careful consideration in determining the management of the patient. Pressure symptoms are the most insistent for relief. Their presence, extent and gravity may be very accurately determined by studying the fundus of the eye. Notwithstanding the desperate conditions embodied in fracture of the base of the skull, about 50 per cent. of the patients surviving the first forty-eight hours following receipt of the injury make a final recovery. The treatment should be directed with a view of relieving shock, stopping hemorrhage, preventing infection and controlling pressure.

Ischemic Myositis: Volkmann's Contracture

Dr. E. M. Sanders, Nashville, Tenn.: Three avenues are open to the surgeon for the treatment of this condition: 1. The method of Jones, in which gradual extension is applied to the fingers and wrist by a specially prepared splint, accompanied by vigorous active and passive motion, hot applications, and electricity. Mild cases can be managed satisfactorily by this method. I have used it with surprisingly good results in some cases, and in all the patients were greatly benefited. The value of this method of treatment depends largely on the promptness of its application, the cooperation of the patient, and the persistence with which it is carried out. 2. The more severe cases cannot be so treated with any degree of satisfaction, and should be subjected to tenoplasty, whereby elongation of the tendons of the affected muscles is accomplished. This should not be done earlier than three months from the establishment of the contracture, as it takes about this length of time for the maximum damage to be done. When the anterior capsule of the wrist joint is permanently contracted, the necessity of capsulotomy should not be overlooked. 3. In the more severe cases, and especially in children, resection of both bones of the forearm, as done by Mikulicz, is justified, and has given a fair percentage of good results in apparently hopeless cases. Before either of these operations is advised, one should remember the increased risk of infection because of the deficient nutrition of the parts, and the resulting adhesions between the tendons; and when the bones are dealt with, also the danger of nonunion and deformity. The prognosis should be guarded, as the end-results are apt to be far from ideal. As a rule, surgeons are in too great a hurry to reduce fractures and apply dressings, and this is especially true of fractures of the forearm and about the elbow in children.

Extirpation of Choroid Plexus in Hydrocephalus.—Only the treatment of the communicating type of hydrocephalus is considered by Dandy. From the results of experiments on animals a new and scientific form of treatment is suggested, by which it is hoped to circumvent the cause. This treatment aims to restore the balance between fluid production and fluid absorption by reducing the production of cerebrospinal fluid to a level where it can be absorbed. By experiments on animals, the following facts have been established: (1) If the foramen of Monro is occluded, a unilateral hydrocephalus results; (2) but if the entire choroid plexus of this ventricle is removed at the time the foramen of Monro is occluded, this ventricle will be obliterated; (3) therefore, cerebrospinal fluid forms from the choroid plexus, and not from the ependyma. (4) Following total occlusion of the aqueduct of Sylvius the development of hydrocephalus is greatly retarded by the extirpation of the choroid plexus of both lateral ventricles. In this experiment the cerebrospinal fluid, which is produced proximal to the obstruction, can be derived only from the choroid plexus of the third ventricle. The conclusion drawn from these experiments is, that if all the choroid plexuses of the four ventricles could be removed, the formation of cerebrospinal fluid would cease and hydrocephalus could not result, or, if present, its development would cease. To cure obstructive hydrocephalus by removal of the choroid plexus, it would be necessary to remove all of the choroid plexuses because there is no absorption in the ventricles; but in communicating hydrocephalus, there is about one fifth of the normal absorption. It would not, therefore, be necessary to remove the entire amount of choroid plexus but to reduce its volume until the amount remaining would not produce cerebrospinal fluid faster than it could be absorbed. In other words, it would be necessary to remove about four fifths of the total amount of choroid plexus to reduce the fluid formation to the 8 to 10 per cent. absorption (one fifth of the normal) which occurs in communicating hydrocephalus. It is not feasible to remove the choroid plexus from the third ventricle and very difficult to extirpate flocculi in the fourth ventricle.

The choroid plexuses of the combined third and fourth ventricles equal about one fifth of the total amount in all the ventricles. The plexuses in the two lateral ventricles therefore comprise about four fifths of the total. A bilateral extirpation from the lateral ventricles should, therefore, reduce the formation of cerebrospinal fluid to a point where it can be absorbed by the restricted patent area of the subarachnoid space. Dandy describes the operation which he has done in four cases of hydrocephalus. All these patients survived the operation, although three died two to four weeks after the operation. One patient has survived a bilateral choroid plexectomy ten months, and shows no evidence that the disease is advancing. During and following the operation the reaction seems to vary directly with the grade of the disease.

Retrograde Intussusception of Sigmoid.—The case reported by Balfour is unique for the reasons that the condition was primary and had not developed as a complication to an intussusception of the usual variety, that it was not a terminal event in peritonitis or obstructive vomiting, and that the method of its recurrence could be observed at operation.

Dangers of Uterine Curettage.—Forty-three cases are cited by Lincoln to emphasize that any intra-uterine instrumentation is a dangerous procedure. The indications for such work practically narrow down to the removal of some products of conception or of bits of tissue for microscopic examination, and even here Lincoln says it is probably better to use the finger or placental forceps in the first instance, and it is somewhat doubtful whether the latter procedure is justifiable unless prepared for immediate removal. A curettage is a major operation not to be undertaken except under the very best conditions, and with every possible precaution, by a careful and skilful surgeon.

Treatment of War Neuroses.—Stewart emphasizes the fact that treatment to be successful must be based on an accurate diagnosis. To arrive at a diagnosis a compete history is of great value. Systematic physical study is required. A hasty or slipshod examination is always bad. The personality of the physician is *an* all-important factor for successful treatment. The environment in which treatment of neurotic patients is to be carried out should be selected carefully. The patient should be withdrawn from the original surroundings under which his symptoms first developed, and placed under the care of a trained neurologic physician, preferably in a specially arranged hospital. Segregation of early cases, each patient having a special tent or room to himself, away from other patients, is of special value, if the patient is made to feel that he is *not* being imprisoned, but that he has been selected for special individual care for a limited period of time, and that meanwhile he is under constant observation. An atmosphere of cheerful, mutual confidence and optimism is essential. The confirmed neurotic, or "hospital-bird" who has wandered from one institution to another, gathering pearls of clinical symptomatology by the way, or, in other words, learning new tricks, is much more refractory to treatment than the recent patient who has not yet been examined or treated. The "hospital-bird" tends also to have a considerable superadded element of malingering, which helps him to play his part with added gusto, whether to bored or to sympathetic audiences. The return of the patient to his own home should, as a rule, be postponed until the cure is practically complete.

Symptoms which have been produced mainly by emotional shock or by suggestion are to be treated chiefly by psychical methods; those due to physical concussion or to exhaustion, chiefly by physical remedies, such as rest, massage, diet, electricity, etc. Those due to intoxications are the cases in which drugs are most likely to be of value in combating individual symptoms, such as tachycardia, insomnia, etc. Other cases may require to be transferred for treatment to a mental hospital. Hence, the importance, at the very outset, of the careful diagnosis and accurate classification of each patient. The particular treatment to be followed is outlined in detail. Speaking of hypnosis, Stewart says that hypnotism is rarely necessary. It is open to the objection that the phenomena of the hypnotic trance are themselves essentially hysterical in character, so that by hypnotizing a hysterical patient, one hysterical condition is replaced by another. Clinical experience has shown that waking suggestions are just as efficacious as those achieved by hypnosis, and their effects are more likely to be permanent.

War Neuroses.—During a period of six or seven months, when in charge of the neurologic ward of a general hospital at the base in France, Russel never saw the symptoms of shell shock in a wounded patient. Later in England, in an orthopedic hospital, he saw a few such cases, but they were always in men wounded rather slightly, not sufficient to have made it necessary to send the man back to England, or in patients who had recovered from a wound, and when there was a question of them returning to France again, the symptoms of shell shock developed. Shell shock was not found in German prisoners. Russel made a detailed study of some sixty cases of psychogenetic conditions picked at random and these showed that the average time in France for the whole of this series was two years and eight months, but excluding eight of these men who did spend a considerable time at the front before breaking down, the average time for the rest is reduced to one year and nine months. Nine had never been there at all. Evidently, the only common experience in all these cases was that they were exposed to danger or under the apprehension of being exposed, and the explanation of shell shock not being found in prisoners, either our own or those of our enemies, is that they were no longer exposed to such danger or were not under the apprehension of it. Russel urges that rational scientific methods should be used in the treatment of these psychogenetic cases.

Histogenesis of Multiple Sclerosis.—The basis of Klingman's investigation rests on four cases of multiple sclerosis. All of the patients were under observation for considerable periods of time and presented sufficient clinical evidence for a positive diagnosis. All of the tissue examined revealed, in general, a uniform histopathology, which is described in detail, but not in toto. The description will be completed in the second paper.

Shell Shock.—The application of the term "shock" to the functional nervous disorders observed in soldiers is greatly deprecated by Dercum. He says that the symptoms are due to hysteria and nothing but hysteria. According to Dercum the proper remedy for shell shock is the strict exclusion from the draft of material alike unserviceable, contaminating and demoralizing, and most expensive from the point of view of military economics. The hysterical person is one burdened with a defective organization, which is expressive of a biologic inferiority. That under the severe nervous overstrain of war, fatigue symptoms should present themselves and often in a pronounced degree, is no more than could have been expected; but this is a very different matter from shell shock.

Spinal Automatism After Spinal Cord Division.—Schaller reports the case of an adult man rendered totally paraplegic following fracture of the tenth dorsal spine and consequent direct injury to the cord. He was first seen one year and three months after injury. Examination disclosed exaggerated inferior tendon reflexes, accompanied by pathologic pyramidal tract signs, marked defense reactions, preserved muscule tonus and patellar clonus, total absence of voluntary motion in lower extremities; involuntary action of sphincters, decubitus ulcers over both hips; absolute anesthesia below the ninth and tenth dorsal radicular skin distribution. Because of the abnormal motor phenomena a compression of the cord was suspected, and a laminectomy performed. A complete division of the cord tissue proper was found. The ends of both cord fragments were trimmed off and preserved for future examination. An effort to suture the two ends of the spinal cord was made and found impossible. Reexamination, in nineteen days after operation, showed the same clinical signs as before operation. The case is cited as a striking example of spinal automatism after cord transection. It is noteworthy particularly because of the long duration of life (almost three years), persistence of the extensor toe reflex; exaggerated patellar and ankle jerks; patellar clonus; automatic bladder and rectum; preserved muscle tonus of normal or increased degree; presence of extensor as well as flexor responses in the same extremity and concomitant flexor and extensor responses of unequal intensity in the muscles of the same extremity.

Spinal Fluid in Postdiphtheritic Paralysis.—The findings in the spinal fluids in the six cases examined by Regan were normal in all instances with a slight exception in one patient where the albumin and globulin content were slightly increased. In no instances has there been any increase in cells, the cell count never exceeding a total of 7 per cm. Lymphocytes were always the predominant type of cell; indeed, in all but one case the only type present. The reduction of Fehling's solution was normal in all six fluids. Macroscopically, the fluids were clear and transparent. In most instances a slight hypertension seemed to exist as indicated by the increased rapidity of flow through the needle and by a positive Macewen sign. Providing the fluid was removed slowly and in small quantities no detrimental effects were observed. In fact, it was thought that at times slight improvement occurred in the condition of the patient following rachiocentesis. The spinal fluids were taken at various stages in the disease from a period shortly after paralysis developed in some cases, until just preceding or following death in others. It seemed rather doubtful, therefore, that a transient meningeal reaction could exist and yet leave no trace at the diverse periods of the disease in which punctures were performed. It is instructive to note that all the patients in the series were suffering from a grave and usually mortal type of paralysis, a type in which central involvement of the nervous system could most be expected.

Infant Morbidity.—Abstracted in The Journal, July 27, 1918, p. 307.

Prognosis in Tuberculous Meningitis.—Van der Bogert ascribes the recovery in his case to the performance of lumbar puncture.

Chronic Vasoconstriction Spots and Their Significance.—The chronic vasoconstriction spots observed in the forearms, hands and face, Tracy says, are found associated with nerve and brain lesions. One or more pigment spots are found nearby. Chronic vasoconstriction spots imply an increased flow of nerve stimuli over the vasoconstrictors involved in the production of the spot, a true hypertonia of the vasoconstrictors involved. The cause of the hypertonia of the vasoconstrictors involved in the chronic spots is probably mechanical, an enmeshment of the fibers in glial or hypertrophic connective tissue, and a consequent constant irritation of the neurones by the pressure of this tissue. The cause of the intensification of the spots observed at times, especially in idiopathic epilepsy, is probably a toxin in the blood stream, the product of a faulty metabolism, that further irritates the abnormal sympathetic neurones. Cases in which peripheral nerve and cord lesions are excluded, point to an organic brain lesion.

Effect of Influenza on Tuberculosis.—The testimony obtained by Hawes from the superintendents of state tuberculosis sanatoriums on this point is that an acute attack of influenza, usually associated with bronchopneumonia, of greater or less severity, has had remarkably little effect on the already existing tuberculous process as far as increasing its spread or its activity is concerned. Hawes' experience in his own work confirms these observations.

Complement Fixation in Tuberculosis.—The complement fixation test for tuberculosis was made by Barnes and Bernton on 279 sanatorium patients. Three hundred and ninety tests were made. The serum was examined within twenty-four hours in all but thirty cases; never later than forty-eight hours. Positive reactions occurred in only about 30 per cent. of progressive cases and in only 9 per cent. of negative sputum cases, hence the test is regarded by the authors as being of but slight value in this series of cases.

Infected Gunshot Injuries of Hip.—Five cases are cited by Mayer to illustrate that in dealing with infected gunshot injuries of the large joints, the first consideration is the life of the patient. In deciding on the best course of treatment the operator should be governed by the principle of removing the pus focus as effectively as possible and with minimal shock to the patient. Simple drainage in the presence of a shattered, infected bone will not suffice. Disarticulation at the hip gives opportunity to clear away the septic focus, but the shock involved is very great. Excision is unquestionably the operation of choice.

The first case cited was one of complete recovery subsequent to extensive purulent coxitis, developing secondarily to an injury to the ramus of the ischium. A satisfactory range of voluntary motion resulted subsequently to the operation. The significant facts in the second case were (1) the prevention of para-articular abscesses by prompt surgical intervention, (2) the excellent functional result after extensive resection, including 1.5 cm. of the great trochanter, (3) the occurrence of a metastatic purulent arthritis of the ankle joint, as an indication of the pyemia likely to be associated with infected gunshot injuries of the hip. The third case differs from the first two in the mild character of the infection, resulting in a serious rather than a purulent coxitis. Resection was indicated because of the gradual extension of the inflammatory process to the acetabulum. Ankylosis resulted, probably due to the fact that comparatively little of the trochanter was removed, thus allowing it to impinge against the roughened surface of the acetabulum. In the fourth case a large retroperitoneal abscess was present at the time of the first operation, but not detected. This led to a second operation and the loss of a part of the shaft of the femur and a shortening of 10 cm.

The fifth case represents the type of arthritis in which, despite the high temperature, nothing was to be gained by an immediate excision of the joint. The septic symptoms were due to a severely infected communited fracture, not joint involvement. Therefore Mayer waited until the joint was walled off completely by granulations, before removing the necrotic head. The functional result, in this case, was poor, owing to the fact that the shaft of the femur was displaced upward and had no hold against the pelvis. It was impossible to overcome the difficulty by traction or by directing the femur toward the acetabulum; therefore, Mayer constructed an artificial acetabulum. The outer surface of the ilium was exposed just above the acetabular margin; an opening was made through the entire thickness of the bone. A section of the cortex of the tibia about 7 cm. long by 3 cm. wide fitted snugly into this hole. Roentgenogram two months later, showed an effective buttress which prevented upward displacement of the femur and enabled the patient to walk.

Electrocardiography and Orthodiagraphy in Management of Disorders of Heart.—Bishop says that every heart has an individuality of its own and every electrocardiograph is just as individual as a man's face or his signature or handwriting. If a patient comes back after a long period he can be identified by his electrocardiograph just as he could by his finger prints. As in the contraction of any other muscle, the heart muscle when it contracts becomes positive at one end and negative at the other end and thus produces an electric current, and while it is not practical to connect a wire to each muscle to demonstrate this, such a test is not necessary. The principle is similar to that of the duplex telegraph, which can carry ten messages over one wire and distribute each to the proper distributing station. In a similar way the different currents run through the heart and there is no diffculty in identifying them because they happen at different times and have certain definite characteristics.

Sawdust Surgical Handrub.—Griffith suggests the use of sawdust as a cleanser for the surgeons hands instead of the usual antiseptics. He claims that it is effective, lessens the skin damage and leaves the operator's hands safe. Sawdust does not clog washbasin wastepipes, for the reason that fine sawdust tends to separate the particles so that they do not lump in running water, and the lightness of the sediment further adapts it to be conveyed unrestricted. The use of sawdust from yellow pine, or fat pine as it is called, sometimes containing much oleoresinous substance of natural antiseptic nature when the turpentine has not been previously extracted from the tree, would prove its worth as a drier of the skin surfaces, especially to replace the chalk and talcum dusting powders where rubber gloves are to be donned. All sawdust for surgeons' use can readily and positively be sterilized by baking. Its adaptation for cleansing away excess oil and scurf and extraneous matter and attached germs from the skin of hands and arms of the surgical operator, aside from being a mere mechanical rub, is not an impractical suggestion.

Two Most Important Signs in Chronic Appendicitis.—The two signs referred to by Morris are: (1) When a chronic irritative appendicitis has registered its nerve impulses on certain sympathetic ganglia for a fairly long time, the muscular coat of the ascending colon becomes wearied. This wearied ascending colon with lax muscular coat remains distended with gas most of the time and gives what Morris calls the "cider barrel sign." Percussion on the left side of the patient's abdomen gives a note reminding one of the cider barrel in October (full) and percussion on the right side of the patient's abdomen gives a note suggestive of the cider barrel in March (empty). (2) The other sign, which, Morris says, is the most important one perhaps, consists in a hypersensitiveness at the site of the fused second and third synpathetic lumbar ganglia. Persistent nerve impulse from an irritated appendix appears to be registered selectively on the fused second and third ganglia causing hyperalgia of more or less permanent character relating to this ganglionic point. By pressing deeply on the abdomen about 1½ inches to the right of the navel and a trifle caudad, the patient feels pain when this particular ganglionic point is pressed on in cases of chronic appendicitis.

Method for Using Dakin's Solution for Continuously Irrigating Mastoid Wound.—Kahn's method is a sort of wound flushing by means of one tube placed in the upper angle of the wound and another tube placed in the lower angle. The irrigating fluid enters above and leaves below. Irrigation thus is continuous, and it can be interrupted at any time.

Acute Cerebrospinal Syphilis.—The cases in the series reported by Qualls in which intraspinal neo-arsphenamin medication was employed seem to have improved more rapidly and improvement was apparently more permanent than in those receiving arsphenamin only. He believes that the administration of mercury to its limit of tolerance in conjunction with intravenous and intraspinal medication of arsphenamin is a potent factor for good. By employment of the proper technic the amount of serum given intraspinally may be increased materially without *depression* or serious after effects, and it is believed with more rapid improvement. In one of the cases the onset and manifestations were of such an acute character that the case could have been easily mistaken for an acute meningitis due to the meningococcus had it not been for the labora[illegible]dings.

Vasomotor Response in Cardiac and Renal Diseases.—A classification of cardiovascular renal disease is offered by the authors as a working hypothesis. The cases are divided into: A. Those with vasomotor response retained and therefore with mobile arterial tree. B. Those with vasomotor response lost or refractory arterial tree. Group B is further divided into: Vasomotor response refractory temporarily or permanently through presence in blood of irremovable pressor substances. Vasomotor response permanently refractory from sclerosis or calcareous degeneration of arterial wall. Fifty-three cases were studied. The results lead the authors to claim that hypertension is never conservative for either heart or kidneys, but always destructive sooner or later to these organs. Hence an effort should always be made to reduce it; if successful the walls of the arterial tree and the heart and kidney compensation will be observed and their decompensation improved or relieved. If unsuccessful no harm will have been done to either heart or kidneys or arteries. Individuals at about middle life should report to their physician as they do to their dentist, so that hypertension may be detected and controlled before becoming refractory, and thereby preventing all the dire aftermath in heart and kidneys and blood vessels, tending toward a fatal termination. Even after hypertension has become apparently refractory, it may yet prove controllable later when not at first and even if permanently uncontrollable, if heart compensation has yet not been disturbed much can be done to conserve cardiac compensation, and even after its failure it may be for a time at least restored.

Treatment of Epidemic Pneumonitis.—The treatment given by Stine and others in 1,020 cases of pneumonia was as follows: Absolute rest in bed of all cases as even the mildest is a potential pneumonia. The wards were kept warm and patients protected from draughts. There was no attempt to control fever by hydrotherapeutic measures. On entering the patient was given Dover's powder, 2.5 to 5 grains, and quinin, 2.5 to 5 grains, repeated every four hours. Medication by mouth was often discontinued on account of nausea. On the appearance of signs of consolidation, that is, areas of bronchial breathing and dullness, camphor, 36 grains, in sterile olive oil was given intramuscularly every eight hours in men and every ten hours in women. In the severe types of pneumonia this dose was given as often as every four hours for four doses and then every eight hours. Some patients received as much as 800 grains in seven days. In the severer cases that did not respond to the camphor, a transfusion of citrated blood from convalescent patients has been done. The results of this procedure were somewhat doubtful. Normal horse serum seemed to give a beneficial result in about the same percentage of cases. Intravenous infusions of solutions of alkaline salts were without results. The results of the treatment of the infection with a vaccine made from killed diplostreptococci are as yet doubtful. The low mortality of 1.3 per cent., is explained as resulting from the early recognition of the extension of the pneumonitis in the alveolar tissue of the lungs, keeping the temperature of the wards at about 75 F., and to the use of large doses of camphor in those cases where pneumonia was suspected.

Medical Treatment of Cancer.—Bulkley reviews the etiology and pathogenesis of cancer. He cites references in support of his belief that cancer is the result of a metabolic disturbance, hence in the treatment regulation of the diet is of prime importance. In fact, he says, diet is the most important part in the treatment and prophylaxis of cancer. Drugs are used only to make the metabolism correct and to keep it so. For this purpose Bulkley prefers acetate of potassium, in doses of from 15 to 30 grains, generally combined with nux vomica and fluid extract of rumex root, given three times daily, half an hour before meals, well diluted. Fluid extract of cascara is commonly added, in doses sufficient to secure full and free daily action of the bowels. Iron and phosphatic preparations are also called for in most cases, even over long periods, and very many other remedies may be needed from time to time to render the metabolism correct. Bulkley says that there is no comparison between the results thus obtained and those claimed by surgeons.

*Intensive Vaccine Treatment of Lung Complications in Present Influenza Epidemic. E. O. Houda.—p. 336.

Vaccine Treatment of Lung Complications of Influenza.—Every case of influenza, with persisting evidences of active disease after the fourth and fifth day, was regarded by Houda as a potential pneumonia because all of them had the findings which preceded the typical evidences in fatal cases, so that Houda is convinced that if untreated they would have developed into the severe types of pneumonia. In all of these beginning pneumonias the usual influenza symptoms were present and all of them had a leukopenia. The intensive vaccine treatment employed consisted of twelve hourly injections of a sensitized pneumostreptococcus vaccine with a total content of 2,000,000,000 of each bacterium, this dosage being given each night and morning until positive evidences of defervescence took place. These evidences usually showed before the fourth dose was given. In no case were more than four doses given. At the end of forty-eight hours there was a marked decrease in the temperature, with a corresponding drop in the pulse rate. After seventy-two hours, the general condition of patients was very similar to the postcritical state of the regular croupous pneumonia. Those who had had consolidation with tubular breathing and dulness still present these signs. These persisted for as long as two weeks before clearing up entirely, with no temperature and normal pulse after the first forty-eight to seventy-two hour period.

"Rheumatism" Analyzed.—Deaderick urges a careful examination before pronouncing a diagnosis of "rheumatism." His analysis showed that there were forty-four cases of arthritis in some form and three of muscular rheumatism, or forty-seven cases to which the term "rheumatism," if permissible at all, might be applicable, and that the diagnosis was entirely inappropriate in 53 per cent. of the cases. Thirty of the forty-four patients gave a history of gonorrhea. In the whole group of fifty-three incorrectly diagnosed cases there were eighteen of syphilis, with a positive Wassermann, eight cases of neuritis, four cases of tuberculosis, four cases of flat foot; three cases of pellagra were typical; two cases each of neurasthenia, arteriosclerosis, sciatica and tabes; one case each of chronic nephritis, chronic gastritis, progressive muscular atrophy, malaria, pernicious anemia and myelitis.

Study of Pellagra.—This study, made in two small towns, pellagra foci in South Carolina showed the disease to have been steadily on the increase from 1907 until 1914, this increase being less rapid, however, during the last three years. The incidence of this disease was slightly higher in the white than in the colored race, although this difference is gradually disappearing. Pellagra was relatively common from the age of 1 year up till puberty, when there seemed to be an abatement during that period, after which it increased again. During pregnancy there was an increased resistance to the disease, but this, in turn, was followed by a decrease of resistance during parturition, when occurrence or recurrence is especially liable to take place. Studies on recovery and recurrence showed the former to be more permanent in children than in adults. As regards the latter, it was found that a year without recurrence was an especially favorable omen. From the standpoint of the spread and location of the disease, the authors found that since 1914 practically all the new cases of pellagra in that community developed while the person was residing in the same house with, or next door to, a pellagrin in the active stage of the disease, or within six months after such exposure. It was further noted that following the installation of a proper sewage system the spread of the disease was almost wholly arrested, all of which tends to lend support to the infection theory regarding the spread and outbreak of pellagra.

Filtrable Virus in Influenza.—The investigations made by the authors and reported briefly in this paper confirm the observations made by Nicolle and Lebailly suggesting the etiologic part played by a filtrable virus in influenza cases. Two rhesus monkeys, inoculated subconjunctivally and intranasally with the filtered sputum from cases of human influenza, became ill on the sixth and seventh day, respectively, that is, after a period corresponding closely with that noted in human cases under similar conditions by Nicolle and Lebailly. Two control monkeys, kept in the same room under similar conditions, manifested no signs of illness during the same period. Of the two inoculated monkeys, one rapidly regained normal health, all symptoms appearing to have subsided by the third day of the attack. The other seemed to be on the mend on the afternoon of the third day, when it was killed for further examination. In the animal the respiratory tract was found to show the presence of a hemorrhagic exudate affecting especially the lower lobes of both lungs. The condition found was in many respects comparable to that noted in certain human cases of influenza in which a fatal issue had supervened before the occurrence of marked secondary infection. In this connection it is interesting to recall the tendency to hemorrhages so often noted during the present influenza epidemic, generally early in the disease. Two rhesus monkeys, at first used as controls and subsequently inoculated, the one with filtered, the other with unfiltered sputum, collected from a case of influenza on the sixth day of the disease, showed no symptoms and remained well.

Common Factor in Disordered Action of Heart.—Murray directs attention to the importance of all debilitating factors in the life history of the individual, which, although disappearing without trace, nevertheless have created a vicious circle which readily recurs, and under any stress will reappear and alter every function of the body, mental and physical.

Fibroma of Trachea.—Horgan's patient was only 9 years of age. When first seen by him, the boy presented all the clinical signs of almost total tracheal occlusion. There was orthopnea and marked stridor, especially during inspiration. The lower sternal and costal cartilages, as well as the upper abdominal parietes and suprasternal notch, were in a state of permanent and very decided retraction. No breath sounds could be heard with the stethoscope in either lung, but a loud vibratory sound was audible over the upper central sternal region. The pharynx and larynx were normal. Examination of the trachea, carried out by means of the Avellis procedure, disclosed what appeared to be a dusky red, globular tumor, situated very low down in the trachea. Horgan performed a low tracheotomy under local anesthesia, but found that the tumor mass lay below the longest tracheotomy tube available. Holding the tracheal rings apart, Horgan inserted a small Luc's nasal forceps in the direction of the bifurcation, grasping and removing a hard pediculated tumor. Breathing at once became easy and consciousness returned. The patient made an uneventful recovery. The specimen proved to be a fibroma, and consisted chiefly of fibrous tissue and blood vessels covered by compound epithelium.

*Value of Germinated Beans in Treatment of Scurvy. H. W. Wiltshire.—p. 811.
*Beer and Scurvy. A. H. Smith.—p. 813.

Germinated Beans in Treatment of Scurvy.—In the hospital in which Wiltshire made his observations, two wards, each containing twenty-seven beds, were specially devoted to the purpose of comparing the therapeutic values of germinated beans and fresh lemon juice in scurvy. Scurvy cases were admitted to these two wards alternately without selection. In one ward each patient was given 4 ounces of fresh lemon juice daily, the juice being expressed in the ward, sweetened slightly, and given as a measured dose by the sister. In the other ward each patient received a portion of germinated beans which had weighed 4 ounces in the dry state, half being taken at dinner and half at tea. In respect of other forms of treatment, such as tonics and local treatment to the mouth, no difference was made between the two wards. Thirty patients were treated throughout with lemon juice, and twenty-seven with beans. Contrasting them as regards severity of disease at the commencement of treatment, those treated with beans were, on the whole, slightly worse. Comparing the results of treatment, there is a small but definite difference in favor of those treated with beans, 70.4 per cent., being cured within four weeks, as against 53.4 per cent., of those treated with lemon juice. These figures favor the bean cases unduly, the real difference being better expressed by the time taken for the gums to return to normal, which was 3.1 weeks for bean cases and 3.4 weeks for lemon cases. In another series of twenty-one cases beans were not given until the patients had failed to make satisfactory progress after an average of four weeks' treatment in hospital by other means. These, although they had shown themselves rather refractory to ordinary treatment, all showed acceleration of progress when put on the beans, and in some the difference was very marked.

Beer and Scurvy.—Beer was held for generations to have considerable value as an antiscrobutic, and was long used as such on sea voyages. The virtue of it was not attributed solely to the various ingredients from which it was brewed but largely to the fermentation itself, and beers were made of different materials and in different ways. Spruce beer and sweetwort were especially useful. Malt which is not "highly dried," as in the modern manner, probably retains much of its potency. But, Smith says, with the elaborating and perfecting of malting and brewing processes, the antiscorbutic element seems to have been largely, if not completely, eliminated from malt beer.

*Endocrine Glands and Dystrophy. V. Hutinel.—p. 617. Conc'n.
Large Doses of Diphtheria Antitoxin. G. Bosc.—p. 648.
*Suprarenal Hemorrhage in Children. J. Comby.—p. 651.

The Ductless Glands and Development of Bones.—In this concluding portion of Hutinel's study of "endocrine glands and bone dystrophies" he discusses the therapeutic indications which emerge from this long study of the general pathology of children. He says that organotherapy does not seem to have fulfilled its promises but he thinks that this is because we have been asking too much of it. We cannot expect it to cure incurable infirmities and deformities. If we distinguish the cases in which it will prove actually useful and reliable, and we are content to wait for the benefit to become apparent and not expect it immediately, effectual and durable results can be counted on with it. It must be confessed, he adds, that notwithstanding the abundant literature on the subject, we are still in the tentative stage. It is only by pursuing the investigations, keeping up observations over years, and supplementing them by animal experimentation, that the profession can hope to obtain a decisive judgment on this great question of the organotherapy of dystrophies.

Out of door life, hygiene, dieting, tonics, etc., are indispensable adjuvants to organotherapy and as there are usually more than one endocrine gland involved, it is important to determine which ones. Tentative treatment and occasional failures are inevitable but experience will gradually clear away the uncertainty. It is wise to begin with small doses, as exaggerated susceptibility is not infrequent. Rachitis in infants develops under the influence of defective feeding and digestive disturbance with superposed damage from acute or chronic infections. All of the organs may have suffered more or less in their development, including the endocrinous glands, and their functional upset may add to the clinical picture. An organ extract might help but again it might not. The main reliance is on diet, cod liver oil, phosphorus, etc. But with rachitis in adolescents, supplementary to general hygiene, a trip to the seashore or mountains, rest for body and mind, with ample regulated exercise, thyroid, pituitary, ovary, testicle, even suprarenal extract may have a decidedly favorable influence. We must bear in mind, however, that rachitis at this age is transient and subsides spontaneously; this is another reason for combating it so that it need not leave deforming traces. In osteomalacia the most brilliant results have been realized with suprarenal treatment, sometimes associated with pituitary and thyroid treatment. In two such cases the inherited syphilis had beforehand been given prolonged intramuscular mercurial treatment with the benzoate. In chronic rheumatism, organ therapy gives the best results when the lesions are of recent development. Thyroid, supplemented with epinephrin or suprarenal capsule or pituitary is generally ordered; ovarian treatment for older girls. In adults there is not much encouragement for organ therapy of chronic rheumatism, except possibly with thyroid and ovarian extract for women, given early. Later, they are only possibly useful adjuvants. To be effectual they must be begun at the start and be long kept up.

When a child keeps small, backward in developing, infantile, and there is reason to assume deficient thyroid functioning, thyroid treatment is absolutely indicated. It should be with large doses, long kept up. It may sometimes be useful to add ovary, testicle, pituitary or suprarenal treatment in addition to the cod liver oil, iron, arsenic or other measures that may be needed. With giant growth and acromegaly there are usually several glands involved, and pituitary treatment is generally futile as the lesions are irreparable. In the obese, and with deformed bones, thyroid treatment is the chief indication at first, and later, pituitary. Ovarian or testicle treatment should be added if the genital organs are backward in developing, plus calcium and iron, and hygienic environment. It is wise to weigh frequently and not to try to reduce the weight too fast. In children that are thin and look as if they had consumption, with trophic disurbances in bones and skin, suprarenal capsule, associated sometimes with pituitary and always with general hygiene, has given encouraging results, undoubtedly because there is a certain degree of suprarenal insufficiency.

Suprarenal Hemorrhage in Children.—Comby analyzes some recent works on hemorrhage in the suprarenals in children. When it is actual apoplexy, it is inevitably fatal, but with anything short of this, with low blood pressure, intermittent cyanosis and asthenia, large and repeated doses of epinephrin are called for, watching over the effect by the arterial pressure. He cites Vollbrach's case in which a girl of 15 presented purpura a year before developing Addison's disease.

Extraction of Projectile in Lung under Screen Control and through Minimal Incision. P. Mauclaire.—p. 488.

Influenza.—Roussy says that between 1889 and 1894 he himself had over a hundred attacks of grip, and his observations on himself as well as on others have convinced him that the virus is a volatile poison in the air around an influenza patient. When breathed by a susceptible person its toxic action is felt at once; it seems to be a species of pathogenic microbe invisible with the most powerful microscopes, and far more virulent than any other known microbes—a kind of living vapor.

Uneven Pupils.—Tournay refers to some cases of miosis resulting from war wounds entailing some deficiency in the cervical sympathetic functioning.

Injections of Sugar in Treatment of Tuberculosis.—Lo Monaco is director of the Institute of Physiologic Chemistry of the University of Rome, and the results of his research on subcutaneous injections of sugar have been widely heralded as the sugar treatment of tuberculosis. He here brings the subject down to date, emphasizing that small doses of sugar promote secretion while large doses check it. He relates that subcutaneous injections of small amounts of sugar increase the secretion of milk in women and in cows, without modifying the quality of the milk. On the other hand, injection of a comparatively large amount reduces or arrests secretion, as also occurs when a compress dipped in a thick solution of sugar (equal parts) is applied to arrest superficial or deep hemorrhages. This solution is kept constantly on hand for this purpose by several surgeons at the large hospital in Rome. It has proved its usefulness after transvesical prostatectomy, splenectomy, operations on the brain, and in uterine hemorrhage. It is constantly used for operations on animals, and has been found effectual in reducing suppuration and hastening the healing of wounds. This action on wounds suggested the use of sugar to reduce expectoration in pulmonary tuberculosis, and Lucherini and Galea, his pupils, applied in several cases these daily injections of sugar solution. Their reports were enthusiastic, saying that the secretions, expectoration, and night sweats subsided. Many private patients after forty-five or fifty injections have suspended the treatment with no return of expectoration to date. Even the moist râles have subsided and several of the patients have returned to work, no longer a danger for others. The treatment is indirect, but there is reason to assume that the process in the lung is tending toward healing.

The only drawbacks of the method are that the injections are painful, and a little cocain has to be added. They are also liable to induce fever of a septic type in some; in others they arrest fever. The sugar treatment displays no efficacy in florid phthisis with grave intoxications. Its field, he reiterates, is in cases in which the acute phase is past and the main symptoms are profuse expectoration and night sweats, with little or no fever, but great debility and emaciation. In such cases the sugar injections may induce actual resurrections. Improvement is manifest by the tenth day. This treatment is very useful also in cases of dilatation of the bronchi, in asthma and in emphysema. The injections are entirely harmless, the toxic dose of sugars being from 10 to 15 gm. per kg. of body weight. There are no contraindications, but the treatment should always be under the supervision of a physician, and he should emphasize that the sugar does not act on the tubercle bacillus directly. When there is no further expectoration, the tubercle bacillus dies out from lack of a suitable medium for its propagation. The sugar injections modify also gastric, pancreatic, biliary, renal and other secretions as well as bronchial secretion. His pupil, Barba, has treated large numbers of the tuberculous by this means and kept them long under supervision. Lo Monaco does not mention the daily dose of sugar injected, but it has been stated elsewhere as 5 gm. of saccharose in 5 c.c. of sterilized distilled water (THE JOURNAL, Sept. 28, 1918, p. 1083).

Pituitary Polyuria.—In a case described there was variable polyuria, more pronounced at night. At times the output of urine measured more fluid than the woman had drunk during the twenty-four hours, but the food eaten did not seem to modify the total output, and the composition of the urine and the functioning of the kidneys seemed normal. The most interesting feature of the case was the constant subsidence of the polyuria when the patient was given the extract of the posterior lobe of the pituitary gland. The effect of this treatment is the touchstone which reveals the pituitary origin of the polyuria. In this case necropsy revealed eight gummatous lesions in the pituitary, mostly in the posterior lobe. The woman succumbed to progressive debility and dehydratation.

Operative Treatment of Tuberculous Glands in the Neck.—Dufourmentel reports that rapid and complete healing was always realized in his cases after excision of tuberculous glands in the neck, and he ascribes this invariable success to his routine procedure of suturing immediately without draining. In more than half of his sixty-three cases the gland burst and pus inundated the field, but his assumption that the pus in such cases is sterile was always confirmed by the healing by primary intention. The clips were removed the sixth day: the fifteenth the patient was sent away to convalesce. The scar later naturally was scarcely perceptible unless there had been a preceding fistula. Operative treatment should be preferred for men, and when there are already scars, or the glands are extremely large. He warns that the teeth and tonsils must be put in order or the glands may be infected anew.

Hygiene in France. Granjux.—p. 380.

Quinin in Prevention of Influenza.—Garin noticed that none of the men being given treatment for malaria developed influenza at Lyons. He sent a questionnaire to the ninety hospitals or hospital sections devoted to the care of malarial soldiers, inquiring as to their experience with influenza this year. Replies were received from forty-six institutions and 61 per cent. reported no cases of influenza among the malarial inmates, and 20 per cent. influenza in a very mild form among them. In 19 per cent. no difference as to the incidence of influenza was noted among the malarial and the nonmalarial. The protection seems to be greater when the malarial are taking both arsenic and quinin. At the Lyons hospital, thirty of the malarial inmates aided in caring for the 300 influenza patients but none of them contracted the disease.

Foreign Body in the Knee.—The knee was bent in irreducible contracture and this and recurring hydrarthrosis were explained by a minute shadow of a scrap of shell at the median posterior superior part of the joint, at the upper part of the anterior aspect of the crossed ligaments.

Fracture of the Scaphoid Bone Without Displacement.—Nothing but the roentgen rays would have allowed the discovery of this fissure in the bone, and only by profile radiograms of the painful and the sound foot. It is indispensable also to apply roentgenography early, before time has modified the aspect of the fissure.

*Compulsory Insurance against Sickness and Accidents. F. de Quervain.—p. 529.
*Plastic Motor Surgery. H. Hoessly.—p. 538.
*Prophylaxis of Endemic Goiter. R. Klinger.—p. 546.

Insurance Against Sickness and Industrial Accidents.—De Quervain reviews his experience with the workings of the new legislation on insurance against sickness and industrial accidents in Switzerland. He comments on the leveling effect of practice among the insured. Some who do not require it get an undue proportion of the physician's time and tendance, while others who need it more get only the same average attention. This is the great drawback of contract practice. Next in importance to this is the danger of the physician's clerical work overshadowing his strictly professional work. The physician must impress on himself that the description of a symptom on his certificate is not a diagnosis. Headache, for example, may warn of nephritis or brain tumor. Trigeminal neuralgia, on the other hand, is usually accepted as merely functional until after the failure of treatment. The same may occur with pain elsewhere and precious time be wasted in case of malignant disease. The insured with acute appendicitis, etc., is not so well off as the man picked up on the street, as the police take the latter to the hospital at once, while the insured, with a perforated gastric ulcer or acute pancreatitis, is kept at home for the insurance medical officer to see what is the matter, and by the time he reaches the surgeon, the latter has no chance for anything except to sign the death certificate. Careful clinical study of the case is a fine thing except when the life depends on an hour more or less. It is better to save a sick man undiagnosed than to let him die correctly diagnosed. De Quervain warns the physicians of his town against this tendency, the dire effects of which are being seen more and more by the surgeons in the hospitals. The opposite tendency is equally disastrous in chronic disease; cancer of the rectum, for instance, being overlooked for weeks, as the bleeding is ascribed to hemorrhoids alone. Many a retrosternal goiter goes unsuspected and the case recorded as emphysema or bronchitis. Intercostal neuralgia may mask spondylitis or cancer of the ribs. If only the term catarrhal affection of the bladder could be stricken from the list, tuberculosis of the kidney might be detected oftener and earlier. He warns in particular against the term sciatica. This may cover almost anything, from diabetes to cancer. All the possibilities must be systematically borne in mind in every case. The correct diagnosis requires examination, and thorough examination takes time, and the time at the insurance physician's disposal has to be mainly taken up with making out the clerical record of the case. This is the evil side of the present law.

The evil side of industrial accident insurance is that the injured workman feels that he has certain rights from being insured which set him apart from other injured persons. He looks on the physician as not his friend, not even a neutral, but the man whose dictum as to the compensation he is to receive will never be as favorable to him as he wants it to be. His first letter, his first call on getting out, are to the lawyer to defend him against the physician, against the insurance company, against society at large, all banded together to prevent his getting his just rights. This state of mind is much more universal than physicians imagine. We must keep it constantly in mind through the entire management of the case. We must apply psychiatric prophylaxis and therapy to help the man overcome the inhibitions engendered by this psychology, and do this—and this is the main point—without letting him notice it. For instance, the first use of a limb after a fracture is always more or less painful and disagreeable, but the noninsured man goes at it as a necessary part of his getting well. The insured man, on the other hand, resists the exercise, postponing it until it can be done without disagreeable sensations. He cannot understand that he, the workman to be compensated, must conform to Nature's laws, as for him there are no duties, only his rights. The more consciously he comprehends this, the greater the inclination to exaggeration and then to simulation. The care of the single patient and the whole practice in workmen's compensation cases must be inspired by prophylaxis against these tendencies of the insured, without letting them suspect our aim. First and foremost is the necessity for treatment of the insured and noninsured together and on an equal footing. Anything that suggests that the insured is a special personage must be combated. The greed of the insured is contagious, and when they are segregated it develops more and more, and tricks are invented and taught to others. Special hospitals for certain industries, etc., may be necessary, but when they can be avoided it is much better to keep the injured workmen, without any discrimination, among the general accident cases.

De Quervain reviews the various industrial accident cases liable to be encountered and the special pitfalls for the unwary diagnostician. He has frequently encountered cases of fracture of the atlas or total luxation of the fifth thoracic vertebra without the slightest apparent injury of the spinal cord, and hence the fracture had escaped detection. Symptoms from the roots may point to the injury unless they are mistaken for rheumatism. A fracture need not be mistaken for a simple sprain or contusion if we recall that pain on axial pressure subsides in a few days, while the sharply circumscribed local pain on pressure of a fracture persists for three or four weeks.

He warns that all injury of nerves must be sought and registered with special care so that an attempt may not be made later to ascribe the nervous trouble to the treatment applied. The axillary nerve with dislocation of the shoulder and the radialis with fracture of the shaft are the ones usually involved. A puncture or stab wound of the tendon sheaths usually heals in two or three days, and the physician seldom has the courage to cut down to the tendon, but fatal sepsis may be the result of abstention or even of too timid an incision. Several short but deep incisions may save the finger functioning and perhaps the life. Many other useful warnings and suggestions for management of industrial accident cases are given and specific instances described in illustration.

Plastic Motor Operations.—Hoessly describes among others his success in enabling the artificial fingers to be moved from the natural sources of energy in the short stump of the left forearm in a case illustrated. The patient was a girl of 16 and the stump was a congenital deformity. The sensibility of the stump was remarkably acute, approximating that of normal fingers. Nine illustrations show the prosthesis devised for this case and the nearthrosis of the elbow which facilitated functioning to such an extent as to suggest the advisability of artificially inducing a nearthrosis of the kind at amputations. The force here is derived mainly from the elbow joint and not from the muscle alone. The girl runs the sewing machine, threads her needles, takes measures, etc., and is self-supporting as a seamstress. In another case of congenital defect of the left hand, ample force for voluntary control of artificial fingers is obtained from the wrist.

Prophylaxis of Endemic Goiter.—Klinger advocates that at least 2 or 4 mg. of iodin should be given to each person daily in experiments in the prophylaxis of goiter. Any amount less than this is futile. Even this totals only from 1 to 1.5 gm. per year.

*Epithelioma Developing on Lupus. C. Vignolo-Lutati.—p. 655.

Aug. 25, 1918, **39**, No. 68

*Serotherapy in Erysipelas and Typhoid. A. Campani and F. Bergolli. —p. 662.

Cancer Developing on Lupus.—Lutati has encountered two cases of cancer developing on lupus, among 107 patients with lupus vulgaris. One was a man of 35 who had had lupus for twenty years. The other was a woman of 26 with lupus of fourteen years' standing. Both died within a month or six weeks after applying for treatment, the carcinoma or epithelioma running a rapidly fatal course, involving cheek, nose and lip. The woman refused an operation and the growth was already inoperable in the man when first seen. In a third case the carcinoma developed in the scar tissue left from erythematous lupus. He thinks that probably scar tissue is always involved in the development of cancer on lupus as this occurs only in old cases in which there is probably more or less cicatricial tissue. One of the advantages of the Finsen treatment is that the healing under it leaves such good scars. In conclusion he cites the figures from five clinics, each with from thirty-one to eighty-six cases of carcinoma on lupus tissue, and from eleven to thirty-six developing on healed lupus lesions.

Intravenous Serotherapy in Erysipelas and Typhoid.—Campani and Bergolli have been using diphtheria antitoxin by the vein in treatment of erysipelas, and report excellent results from it. They tried antistreptococcus serum at first but found the diphtheria antitoxin more potent. They gave this treatment only in the graver cases, with fever, delirium and prostration, but without abscesses. Three of forty-eight soldiers treated with the usual measures died, but none died given this intravenous treatment. The dose was 10 c.c. representing 5,000 units. The results justify, they think, that this treatment should be systematically given the preference in the graver and rebellious cases. In typhoid the experience was about the same, only that of all the vaccines and serums tried antimeningococcus serum seemed most effectual. They give the details of seven typical cases to show the efficacy of this nonspecific serotherapy. Antistreptococcus serum has not proved effectual in erysipelas nor antityphoid serum in typhus, according to the general consensus of opinion, but this nonspecific serotherapy reduced the mortality appreciably in his cases although it was applied only in the gravest forms of the disease. The prompt return of consciousness and the euphoria were the most striking effects at first, although the drop in the temperature was impressive. No phenomena suggesting anaphylaxis were observed in any instance. From three to five injections were made by the vein, on successive days, using 10, 20 or 30 c.c. at last.

Aerophagia of Nasopharyngeal Origin. G. Bilancioni.—p. 1171.
*Rupture of Spleen. B. Masci.—p. 1174.

Absent Knee-Jerk in the Healthy.—Garbini remarks that in the two apparently healthy and robust young men, brothers, in whom it was impossible to elicit the knee-jerk, as also in eight similar cases on record, one of the parents had a history of syphilis although no trace of it was evident in the children.

Amebic Dysentery.—Pontano emphasizes that the demobilization of the troops will probably bring cases of amebic dysentery into current medical practice, and he here reviews our present knowledge on diagnosis and treatment. Emetin, he asserts, given in time will ward off complications as well as recurrences. When the amebic is associated with bacillary dysentery, serotherapy should be pushed in addition, from 20 to 40 c.c. a day.

Rupture of Spleen.—A fall from a window caused such concussion of the brain and shock that several hours elapsed before the robust girl recovered consciousness, and no symptoms on the part of the abdomen could be detected before this. Then it was discovered that the spleen had been ruptured and torn completely off its pedicle although there were no signs of contusion of chest or abdomen. The vessels in the pedicle had spontaneously ceased bleeding. The spleen was found absolutely sound otherwise.

Present Status of Operative Treatment of Tuberculosis of Male Genital Organs. E. Aievoli.—p. 919.

Indoxyl in the Urine.—The results of Cantelli's research suggest that indoxyl is not a normal constituent of the urine, and is not present in certain forms of sickness. But it was found in some cases of appendicitis and of occlusion of the colon. This apparently indicates that the indoxyl in the feces is of autochthonous origin, dependent on special conditions in the bowel resulting from partial or complete closure of the lumen.

Roentgen Localization of Foreign Bodies.—Soresi fastens the limb to be examined in a frame to hold it immovable, as shown in illustrations. Very useful is a little device with blades and handles like forceps. One blade terminates in a lead ring, the other blade in a small pad which is dipped in ink. When the hand releases the upper handle the pad drops in the center of the lead ring. This marks the spot on the skin as the foreign body is seen with the rays and centered in the lead ring. By examining from different points and marking the spot casting a shadow, the foreign body is located with precision without any calculations, etc.

Case of Thrombosis of Mesenteric Vessels. L. Razetti.—p. 216.
*Gastro-Enterostomy for Stenosis of Pylorus. Razetti.—p. 217.

Relapsing Fever in Venezuela.—Bello gives the details of six cases of autochthonous relapsing fever at San Cristóbal. The spirochete was cultivated from the blood of all, including one boy of 5 who had four paroxysms of fever. Treatment was merely symptomatic in this and some of the other cases, but two adult patients were given 0.3 or 0.45 gm. of neo-arsphenamin by the vein. Bugs of the cimex and flea families or ticks were found in the patients' homes, but the evidence seems to incriminate more the ticks in the transmission of the disease.

Stenosis of the Pylorus.—Razetti reports a case of stenosis of the pylorus which he says is the third operative case on record at Caracas, and the first one in which the posterior transmesocolic gastrojejunostomy completely cured the patient.

*Intravenous Treatment of General Paresis. E. F. Sanz.—p. 187.
Sulphur in Psoriasis. J. F. de la Portilla.—p. 189.

Thrombosis in Mesenteric Vessels.—Avellan ascribes to thrombosis and embolism in the mesenteric vessels a certain proportion of fatalities after abdominal operations in which forceps with elastic blades were used. They injure the intima of the vessels, rendering the inner surface uneven, while the blood accumulates in the vessel below the compression—all factors which favor thrombosis. They can all be avoided by using long suture threads, passed through the stomach and loop of intestine, the ends of each left long, to lift the organs by, doing away with the necessity for forceps. In a case described, a volvulus seemed by exclusion to be the explanation for the ileus, but the laparotomy revealed embolism in the superior mesenteric artery. The man of 72 had atheromatous changes in the aorta, and embolism from this caused disturbances requiring resection of over 4 feet of the small intestine. The first symptom in the case had been sudden acute pain in the region in the vicinity of the umbilicus, soon after eating, accompanied by vomiting and rigidity of the abdominal wall in the region of the umbilicus. In a recent compilation of 200 cases, the mortality was 94 per cent. In 41 per cent. of the cases blood in the stools was an early sign of the mesenteric thrombosis or embolism.

Treatment of General Paresis.—Sanz calls attention to the great benefit derived in two cases of general paresis from intravenous injections of neo-arsphenamin or mercuric cyanid. One patient was a woman of 50, the other a man of 58. The latter was given thirty injections of the mercury preparation and eight of the neo-arsphenamin, in graduated doses, with potassium iodid internally. In the course of two months the improvement was striking, and the man was able to return to his responsible business position.

Prophylaxis of Serum Sickness.—See abstract 96 in The Journal, Jan. 18, 1919, p. 232.

Care of Infants Separated from Their Mothers.—Uruguay has a law which places the nurslings of women who go out to take positions as wetnurses, and all children under 2 who are separated from their mothers, under the care of the state and community. Acuña urges the adoption of a similar law in Argentina, and outlines a model bill for the purpose. There is supposed to be already a register for wetnurses with official supervision of the infants left behind at home, but this Oficina de Nodrizas is of little practical use, the wetnurses not taking the trouble to register and the public not realizing the advantages of a registered wetnurse with her health certificate. Registration should be made compulsory, and the person caring for the infant separated from its mother should be compelled to bring it for inspection every two weeks, and in case of sickness take it to the nearest dispensary and notify the Oficina de Nodrizas. The Roussel law in France specifies six months as the lowest age at which the mother can leave her child to take a position as wetnurse, but Acuña accepts five months as the limit. Persons caring for infants separated from their mothers should also register, and have their health and home inspected.

Neuralgia of the Testicle.—Nin Posadas noticed that after an operation for varicocele by any method except that of extensive resection of the vaginalis, there was liable to be pain, generally accepted as neuralgia of the testicle or irritable testicle. His study of these cases, however, as in other cases with pains in the testicle convinced him that there was some organic basis for the pain although nothing pathologic could be seen. By pinching the vaginalis and palpating the testicle he found evidence of adhesions, and with a simple operation under local anesthesia he succeeded in breaking up these adhesions and curing at one stroke the "neuralgia" or "irritability" which had long tormented the patients. Eight typical cases are described in detail. There is usually a history of acute or chronic venereal disease or of trauma, and the vaginalis process may be of the adhesive type or fibrous or both. He could find no record in the literature of this unsuspected adhesive vaginalitis as the cause of the disturbances until, in 1912, Bellenger and Elder reported a case of intense neuralgia of the testicle cured by removal of the testicle. After its removal the discovery of minute adhesions explained the pains.

Plastic Motor Surgery.—Arana describes with twenty illustrations his method of making a single loop in the stump of a leg after amputation to utilize the motor forces still left for voluntary control of the prosthesis. He also describes with illustrations the procedures devised by others, and the principles involved. With his method the plastic motor in one case described has a potential force of 3 kilograms with 2 cm. of excursion. The tunnels were solidly lined with epidermis by the tenth day after the operation. He makes four incisions from 8 to 15 cm. long on different sides of the stump and resects the end of the bone in the stump. The skin between the four incisions is loosened to make four bridges, all well supplied with nerves and blood. Muscles that are not to be utilized and that are in the way are resected also. Then the loosened up skin forming the anterior and the posterior bridges is drawn down into two incisions which meet in the depths to form a tunnel. The skin is sutured together there and thus a skin lining for the whole tunnel is provided, first on one side of the tunnel and then on the other. A roll of gauze is then worked into the tunnel which is soon ready for use and is able to vitalize the artificial limb to a surprising extent by the loop formed by the sutured muscles.

*Pulverized Bile as Aid in Determination of Typhoid Bacilli in Water and in Blood. H. Toyoda.—p. 219.

Japanese River Fever.—This first instalment of this report on extensive research on tsutsugamushi disease is accompanied by three colored plates and several other illustrations. The article is in German, and describes experiments on laboratory animals and monkeys with successful inoculation by means of infected mites. The Japanese word *mushi* means "mite," and the present research has confirmed beyond question that the disease is contracted from the bite of a mite or acarus. From one to four of these mites were found on fifteen of twenty-six persons working on the river bank in the infested regions. Some of them had had the disease in previous years, but others had showed no signs of it at any time, so that not all the mites are infected.

Acceleration of Phagocytosis in Citrated Blood as Test for Tuberculosis.—Otani writes in English to call attention to the acceleration of phagocytosis by citrated blood when the blood comes from a tuberculous subject. Comparison with the opsonic index shows much more active phagocytosis with tuberculous than with normal blood. In 82 clinically normal cases the phagocytosis was weak in 56 and active in only 13, while in 100 tuberculous cases only slight phagocytosis was observed in 3 while 89 showed very active phagocytosis. His tabulated findings seem to demonstrate that in this activation of phagocytosis we have a specific reaction which promises to have important diagnostic value. He made an emulsion of virulent tubercle bacilli with 1.5 per cent. sodium citrate (containing 0.85 per cent. sodium chlorid), one volume of which was mixed with an equal volume of fresh blood. The phagocytosis was then observed. It was much more active in tuberculous than in normal blood. In cases in which apparently normal blood showed lively phagocytosis, the tuberculin test revealed that tuberculosis was already installed. The opsonic index fails to show any distinction between normal and tuberculous blood in respect to the phagocytosis. However, the virulence of the bacilli is a modifying factor, as with only slightly virulent bacilli the phagocytosis may be the same in all specimens of blood.

Desiccated Ox Gall in Bacteriologic Work.—As typhoid bacilli thrive on bile better than many saprophytic bacteria, Toyoda inoculates the culture medium as usual and then adds desiccated and pulverized bile to it. By this enrichment procedure even as few as ten typhoid bacilli per 100 c.c. of water can be always experimentally cultivated from it. Applying this technic to 150 different sources of the water supply revealed typhoid bacilli in four while with other technics only one was found contaminated. In testing typhoid blood, an 8 or 10 per cent. bile medium gave the best results in experimental research and an 8 per cent. in the clinic. The desiccated gall can be kept constantly on hand and is ready to use as needed. For the blood test he prepares a culture medium with 3 gm. pulverized gall; 1 gm. peptone; 0.5 gm. sodium chlorid and 100 c.c. water. In testing water he adds to 100 c.c. of the water a solution of 1 gm. peptone; 2.5 gm. sodium sulphate; 0.5 gm. sodium chlorid and 7 or 8 c.c. distilled water, and keeps it at 37 C. for eight hours to give the typhoid bacilli a chance to proliferate. The culture medium is then treated with a solution of the desiccated gall (3 gm. of the bile powder to 7 or 8 c.c. of distilled water), and 1 c.c. of a solution of 0.1 gm. kristallviolet in 100 c.c. of sterilized distilled water. This checks the development of other germs in the water. After standing for ten or sixteen hours at 37 C., a small amount of this culture fluid is transferred to Endo agar, making a series of tests. He prepares the fresh ox gall by heating in a Koch steamer and filtering, then it is desiccated and pulverized.

Tuberculous Porphyry Spleen.—The diagnosis during life had been splenomegaly with probable lymphogranulomatosis, but necropsy failed to reveal any enlarged lymph glands and no foci were found in the liver, while the spleen showed advanced tuberculous changes and an aspect of the cut surface resembling that of porphyry. It had evidently become infected from an old latent apical focus. If it had been removed when first affected, the secondary liver and peritoneum tuberculous lesions might have been warded off. An exploratory puncture or incision might have cleared up the case in time. The patient was a man of 67.

Criminal Abortion.—The woman succumbed to what seemed to be a combination of hemorrhagic nephritis, peritonitis with urobilinuria suggesting pathologic conditions in the liver, blood in vomit and stools and psychic changes, with terminal uremic coma. Enough oleum sabinae was found in the cadaver to explain the fatal nephritis and probably the abortion, as the woman confessed to taking it for that purpose.

Reform in Medical Education.—Van Rijnberk refers to a recent book with this title published by Prof. J. Schwalbe, the editor of the *Deutsche medizinische Wochenschrift*. He insists that the curriculum should be revised at least every five years; the necessity for thoroughgoing changes now has been emphasized by the war. It has demonstrated the excessive proportion of specialists, and the necessity for training physicians to be less dependent on specialists. Schwalbe urges reform in two directions, by training the medical students in practical application of what they are taught, teaching them by letting them do things themselves instead of merely watching the professor do them, and by giving the student a training in philosophy. Elementary logic, philosophy and psychology should be a compulsory part of medical education. This provides a common platform on which all cultivated minds meet on an equal footing, while teaching him the use of the tools with which he is to build up his own knowledge. On the practical side, the students should take part in operations, and be allowed to operate themselves, under good control, as often as possible. Especially in gynecology and obstetrics, looking on is futile; the student must do the work himself.

Schwalbe urges that all hospitals, large and small, should be utilized for practical instruction of the students in internal medicine. He says that all the training the student ever gets now in disease of the throat, nose, ear, skin and sexual organs is merely enough to recognize the condition so that a specialist can be called in to treat it. He declares that students should be trained so they can treat these as well as diagnose them, instead of being merely a directory for the addresses of specialists. He says of instruction in pediatrics that its black side is the diagnosis and treatment of sickness in infants. Sickness in older children much resembles the same in adults, but still one semester of children's diseases is important. The students should be thoroughly grounded in social medicine and hygiene, occupational hygiene, school hygiene, medical legislation, and insurance against industrial accidents. The care and feeding of the sick should be taught both in theory and in practice. The students should be trained in cooking for the sick as well as in the bacteriologic laboratory and in the pharmacy. He insists that there should be a chair for pathologic physiology, general and experimental. If a separate chair is not available, a laboratory for this could be placed in charge of the physiology or pharmacology institutes. In conclusion he declares that more theoretical and practical training in orthopedics, mechanotherapy and massage is also indispensable.

The Significance of Occult Blood in the Stools.—Koopman reports experiences and cites some recently published by others which throw discredit on the finding of occult blood in the stools as a sign of ulcer or cancer. Baumstark reports positive findings now and then in the most diverse pathologic conditions, and others have recently published extremely contradictory findings. Wolff and Daw, for example, found occult blood in 92 per cent. of their cases of trichocephaliasis while Davidsohn obtained only negative results. Rosenthal reported in 1916 negative findings in 100 per cent. of his duodenal ulcer cases, and others found positive findings infrequent. In Koopman's own experience, occult blood was found in the stools only in 2 of 17 certain cases of duodenal ulcer and only in 3 of 7 cases of gastric ulcer. In one particularly striking case a young soldier for nearly three months had complained of pain in the stomach about an hour after eating. The lower margin of the stomach was 1 cm. above the umbilicus. There was no tenderness, and repeated tests for blood in the stools were constantly negative although the young man's diet was not restricted (except meat), and he was strolling about the grounds all day long. The thread impregnation test was negative when applied on three occasions. After a test breakfast, the acidity figure was 20, the total acidity 40, the stratification coefficient 1:2. The young man would have been sent back to service, labeled neurasthenia, if it had not been for a sudden extremely severe hemorrhage from the stomach one morning. Even in cases with a positive thread test, there was often no blood to be detected in the stools.

It is possible for an ulcer to bleed a little and the blood to become disintegrated and absorbed before it reaches the anus. Boas has reported a case with constantly negative findings although a large tumor could be palpated in the cecum. The operation showed that the tumor was of tuberculous origin. Koopman reports a case the counterpart of this, only that the large tuberculous tumor in the [illegible] s accompanied by a strongly positive benzidin reaction in the stools, even with the patient in bed on a milk diet. Boas' assertion that occult blood testifies in favor of cancer and against tuberculosis is thus shown to be erroneous. Koopman noticed that whenever the tests for soluble albumin in the stools were positive, occult blood was always found. He suggests that the whole benzidin reaction may be merely an indication of the presence of dissolved albumin—the blood reaction merely a special form of it. On the whole, Koopman reiterates, the significance of occult blood in the stools is slight. It is more often liable to lead to false than to correct conclusions. A number of writers recently have warned that the Wagner reaction is unreliable, but Boas' chief data were based on this. The spectroscopic method, according to Snapper, seems to promise greater reliability.

Hydrocyanic Acid as Antidote for Digalen and Veratrin.—Bastert reports research on frogs' hearts which demonstrated that when the heart action had been arrested by toxic action from digalen or veratrin, the heart could be resuscitated and started to beating again by the action of hydrocyanic acid. The reverse also occurs, digalen or veratrin resuscitating the heart arrested with the hydrocyanic acid. The resuscitation, however, is not permanent, the heart action becoming arrested again sooner or later. Other phenomena observed were that the heart poisoned with digalen to its complete arrest, started to beat again when the pressure was raised, while with hydrocyanic acid arrest, it started to beat again only when the pressure was lowered. The hydrocyanic acid arrests the heart in diastole, and overcomes the arrest when it occurs in systole. It thus acts like the potassium in Ringer's fluid. The tracings from ten different tests are reproduced in detail.

Vincent's Angina.—The severe ulceromembranous sore throat had developed in a woman already much debilitated by two years of lymphatic leukemia. It was known that she was unable to stand arsphenamin, so this was applied only locally. It had a powerful curative action on the lesions in the throat and mouth, but it proved impossible, even for the specialist, to apply it as effectually in the nose, and the patient died. The malignant course was evidently due to the underlying leukemia.

Uterine Cancers That Do Not Bleed.—Boerma reports a case of the infiltrating form of uterine cancer in which pain in one thigh was the only symptom. There was no discharge, no bleeding; the cervix felt smooth but unusually hard. Only examination in general anesthesia revealed the inoperable condition. Another woman, 70 years old, complained of persisting pain in abdomen and lumbar region, but was apparently in good health otherwise, no bleeding, no discharge, but an inoperable tumor was found in the cervix.

*Purpura. C. Johannessen.—p. 1209.
*Treatment of Hemoptysis. N. Lunde.—p. 1253.
Vagotony and Its Clinical Importance. L. Dedichen.—p. 1260.

Purpura.—Johannessen reviews the literature on purpura since Werlhof's first description in 1775 of a mild form of purpura to the recent descriptions of the form with joint and intestinal manifestations. In the mild group the blood platelets disappear more or less completely from the blood while this does not occur in the second group. The purpura in this second group is always associated with some infection, and it seems to be of an anaphylactoid nature. The purpura may be of a chronic intermittent type, with joint lesions, urticaria, colic and intestinal hemorrhage or albuminuria and hemorrhagic nephritis, or polyneuritis, or it may be simple purpura. Or the purpura may be of an acute or subacute infectious type or it may run a fulminating course, Henoch's purpura fulminans. Johannessen reports the details of some cases representing each of these different types. The prognosis is favorable only in the chronic intermittent forms, and not in all of these, especially as the primary infection is liable to entail valvular or kidney trouble or debility that invites tuberculosis.

Purpura displays a heredity and familial tendency. Children with the exudative diathesis or tuberculous taint are peculiarly subject to it, so that improvement of conditions in this respect aids in prophylaxis. Salicylic medication is called for in every case of rheumatic purpura, and it should be pushed. Recent research has confirmed anew that the coagulation time is normal. The trouble seems to be some paralysis of the capillary elements, the result being a notable vasodilatation. This dilatation of the capillaries allows the blood to seep through, and calcium counteracts this vasodilatation. He found this extremely effectual in a recent case of melena neonatorum, which is evidently a manifestation of purpura. The child was born one month before term and the second day it passed pure blood with the meconium. In the course of the night it was given 6 gm. calcium acetate powder (*acet. calcic. pulv.*) and there was no visible blood in the stools thereafter. The blood count showed 2,040,000 reds and 6,160 whites with 300 blood plates to each 2,010 reds. A subcutaneous injection of 10 c.c. of a 10 per cent. solution of gelatin in 40 c.c. of saline was also given and 0.12 gm. pulverized camphor by the mouth. The gelatin injection was repeated the following day. The calcium was suspended the third day and the child rapidly recuperated and is now in the best of health.

Epinephrin is also useful to arrest the paralysis of the contractile elements of the sympathetic nerve terminals, which is a feature of anaphylactoid purpura. From 0.1 to 0.3 c.c. of the 1 per thousand solution can be injected subcutaneously several times a day. It is ineffectual by the mouth. Administration of epinephrin conforms also to Friedrichsen's theory of the nature of purpura. With abdominal purpura the colic pains may be agonizing. Dieting does not help and warm applications give little relief. Atropin paralyzes the irritated terminals of the vagus nerve in the intestines and thus has a sedative action. He gives it by the mouth or subcutaneously in a 1 per thousand solution.

A foreign albumin seems the most effectual of all treatment for anaphylactoid purpura. Especially gelatin, which is nothing but a heterogenous albumin. It is most active given subcutaneously, about 10 c.c. of a 10 per cent. solution, repeated eventually. It can be given in enemas but is far less effectual. Older children and adults can take it in the form of a pudding. Heubner gives it in a 15 per cent. solution with syrup of raspberry, a tablespoonful every second hour. Serum has proved effectual also but peptone seems to answer the same purpose and is more readily available. Given in doses of from 4 to 10 c.c. of a mixture of 5 parts peptone and 0.5 parts sodium chlorid with 100 parts distilled water, the effect seemed to be completely analogous to that of serum treatment and diphtheria antitoxin. Glanzmann explains its action as a desensitization, an antianaphylaxis from the saturation of the antibody by the peptone. It is by the same mechanism that a small preliminary injection wards off the anaphylactic shock when the main injection is given. In the next instalment the hemorrhagic type of purpura will be analyzed.

Treatment of Hemoptysis.—Lunde states that repose and tranquilizing measures proved all that was necessary in thirteen of twenty-four cases of hemoptysis, but in the others more active measures were required. He found that the hemorrhage stopped at once after injection of 3 c.c. of 20 per cent. camphorated oil, with no other measures except in two cases the limbs were wound to expel the blood as the repeated bleeding had been so profuse. In these cases some small artery must have ruptured. The camphorated oil injection also arrested the hemorrhage in a case of severe epistaxis, and this without tamponing. There was a slight renewal of the epistaxis two and five weeks later. Alexander has advocated camphorated oil for hemoptysis, and Weismayr has confirmed its efficacy, but Lunde discovered it for himself when injecting camphorated oil for another purpose. While attempting to make an artificial pneumothorax, the patient collapsed. The camphorated oil cured the collapse and with it the tendency to bleeding from the lungs during the six months to date. Without this direct and convincing experience he would never have ventured to inject this heart tonic for this purpose. In every one of the eleven patients thus treated the hemorrhage was arrested in a few minutes just as if a finger had been pressed on the bleeding point. He theorizes to explain its action, which seems to be of a dual or manifold nature.

HEMOLYTIC STREPTOCOCCI

WITH SPECIAL REFERENCE TO THEIR RÔLE IN ACUTE RESPIRATORY INFECTIONS *

DAVID J. DAVIS, M.D.
CHICAGO

It seems opportune to discuss the subject of hemolytic streptococci at this time, because during and following such a serious respiratory epidemic as is at present prevailing, these streptococci in one way or another play an important rôle. So extensive is the subject that I can only select points here and there for discussion, and even of these I must speak in more or less general terms.

DEFINITION

By "hemolytic streptococci" I mean the streptococci which on plain blood agar plates cause a wide, clear, complete zone of hemolysis about a small, central gray colony. This zone is usually from 2 to 4 mm. across, but under varying conditions may be less or considerably more. Broth cultures of these streptococci, when added to suspensions of red corpuscles, will hemolyze them in vitro, a test which is also commonly used. This term does not include those common streptococci which, especially in dilute blood mediums or after several days, may cause atypical, colored or incomplete zones of hemolysis. Furthermore, it should be understood that the hemolytic streptococci do not constitute a single variety or genus. Hemolysis is a property common to a number of kinds of streptococci that differ decidedly in other respects.

CLASSIFICATION

With the appearance of Schottmüller's[1] classification in 1903, the old term *Streptococcus pyogenes* was discarded by many for the terms *S. viridans*, *S. hemolyticus* and *S. mucosus*, the three varieties into which streptococci were subdivided, largely on the basis of their reaction and appearance on blood mediums.

Only a few months later, indeed, almost simultaneously with the work of Schottmüller, similar observations and classifications were made and used in this country by Weaver, Hektoen, Ruediger, Rosenow and others. Since then, especially in the Central West, this method of study has been greatly extended and of late years has come into general use in the study of this group of bacteria.

I shall not discuss in detail the various classifications but only refer briefly to those based largely on hemolysis. Holman[2] first used it for classifying streptococci in conjunction with their fermentative reactions. On this basis he recognizes eight different varieties of hemolytic streptococci, to each of which he has given a specific name. Smith and Brown[3] divided hemolytic streptococci into an alpha and a beta type on the basis largely of the degree of hemolysis. The former causes a narrow zone of incomplete hemolysis about the colony, whereas the beta type causes a clear, wide zone of hemolysis, which is complete under and in close proximity to the central colony. It is a useful point for differential purposes. In Andrewes and Horder's[4] classification, two of their varieties, *S. pyogenes* and *S. anginosus*, are hemolytic.

Everything considered, the classification of Holman is perhaps the most useful and convenient, especially when dealing with pathogenic streptococci, and I myself prefer it. It cannot, however, be considered satisfactory in every respect. I have had occasion to study the streptococci in milk, and find especially in nonpasteurized milk streptococci forming wide, clear zones of hemolysis, some of which ferment lactose and salicin but not mannite. According to Holman's scheme, such organisms would fall into his group of *S. pyogenes*. In other respects, however, they are very different from *S. pyogenes*. They rapidly acidify and coagulate milk even at 20 C., and are on the whole much more heat resistant than the pathogenic streptococci. Morphologically, they are more elongated, and in milk tend to grow as diplococci and short chains. For rabbits, and no doubt human beings, these hemolytic milk streptococci have little or no pathogenicity, whereas *S. pyogenes*, as a group, is highly virulent. Indeed, this milk streptococcus is quite like ordinary *Streptococcus lacticus* in all respects except hemolysis, and I prefer to speak of it as a hemolytic *Streptococcus lacticus*. Yet should we apply Holman's classification, we should place these common milk cocci with a highly virulent group, *S. pyogenes*, with which they have few properties in common.

One point may be appropriately emphasized here: Often, especially in current literature, the term *Streptococcus hemolyticus* is used. Since we know that there are at least several kinds of streptococci that cause hemolysis, the use of the binominal *S. hemolyticus* is misleading in that it conveys the idea that there is one definite streptococcus designated thereby, which is not true. Holman's scheme of classification and nomenclature is here helpful in that he has differentiated and named at least some of the several hemolytic varieties.

---

* From the Department of Pathology and Bacteriology, University of Illinois College of Medicine.

[1] Schottmüller: München. med. Wchnschr. 50: 849, 1903.

[2] Holman: J. M. Res. 34: 377, 1916.

[3] Smith and Brown: J. M. Res. 31: 455, 1914.

[4] Andrewes and Horder: Lancet 2: 706, 1906.

Since there are several hemolytic streptococci, I shall not attempt to discuss them all, but will limit myself to those streptococci that are pathogenic for man, or at least potentially so, and will refer to them as pathogenic hemolytic streptococci, understanding that here are included several different varieties, though possessing many important properties in common. They are the organisms commonly referred to as *S. hemolyticus* and roughly also as *S. pyogenes*.

Morphologically, they are spherical or slightly oval, and form definite chains, often quite long, though in the tissues if rapidly multiplying they are frequently seen in pairs or short chains. In the chain, pairing is noted often, though not to the extent seen in pneumococci or in the green streptococci. Their reaction on sugars is varied and, as we have already seen, on this basis they may be classified. Many strains ferment lactose and salicin; a few ferment mannite.

POISONOUS PRODUCTS

Our knowledge of their poisonous products is meager, though no doubt they produce highly toxic bodies. Their hemolytic activity is caused by a hemolysin called streptolysin, and is produced both in vivo and in vitro. According to Ruediger,[5] who studied this substance in detail, it has the structure of a true soluble toxin with a haptophore and a toxophore group. On injection into animals, it gives rise to a specific antibody (Besredka). In severe infections, hemolysis may occur in the vessels in animals and in man with resulting hemoglobinemia. Streptolysin, however, does not appear to be the most important poison produced, since it is not highly toxic and its production does not parallel the intensity of the infection. Nor are the important lesions produced of such a nature as to lead one to think they are caused by the hemolysin. Hemolytic streptococci are not dangerous primarily because they are hemolytic. Some nonhemolytic streptococci are far more dangerous than the hemolytic varieties.

Recently Clark and Felton[6] reported that by growing hemolytic streptococci (isolated from Army camp bronchopneumonias) in rabbit's blood diluted with Locke's solution they obtained a filtrable toxic product which kills rabbits at times in doses of 0.5 c.c. per kilogram intravenously. Its formation is in some way dependent on hemoglobin, but the poison is nonhemolytic in vivo and in vitro. They report that its introduction into a rabbit will immunize both against the poison and against living streptococci. I am not aware that this work has been confirmed. If repeated successfully, it will make an important step in our knowledge of these organisms.

Filtrates of old cultures are only very slightly toxic, and the dead bodies of streptococci either highly or slightly virulent, killed in various ways, can be injected into animals and man in relatively large doses without marked toxic symptoms. They behave in this respect quite like numerous other pathogenic bacteria whose poison lies closely bound with the bacterial cell and to which we apply the term "endotoxin." Practically nothing is known about it.

VIRULENCE

The aggressive and invasive properties of streptococci deserve first consideration, for under certain conditions no other organism known manifests such varied and extensive activities. Aggressins in the sense of Bail have been described, but how they act is not certain. I am inclined more and more to regard the existence of a capsular substance about these streptococci as of considerable, perhaps fundamental, significance. We know very well the virulence of *Streptococcus* or *Pneumococcus mucosus*. I have tested many strains, and all, even those of relatively low virulence, if injected into animals, can be made to reveal a capsule. The highly virulent streptococci, those, for example, from milk epidemics, readily show a capsule in sputum, exudate or blood. Generally, the more virulent the organism, the more distinct is the capsule and the less susceptible are the cocci to phagocytosis. In the streptopneumococcus group, many facts point to a parallelism between capsule substance and virulence.

The virulence of hemolytic streptococci seems to vary markedly for man. This property is so intimately bound up with invasive properties and with the resistance and immunity of the host that analysis of this factor is difficult. In the human being, marked differences in the intensity of infection are commonly observed, though caused by streptococci which, when isolated, are apparently alike, and on animal inoculation show little difference in virulence. To sum up many observations on the virulence of different strains for rabbits, one practically never encounters a hemolytic streptococcus that will kill a 1,000 gm. rabbit in doses of less than 0.5 c.c. of a twenty-four hour serum broth culture intravenously. Usually the highly virulent human strains require larger doses (1 c.c.) to kill or to cause joint and other lesions in rabbits. Guinea-pigs are distinctly less susceptible than rabbits. On the other hand, hemolytic streptococci, with the exception of the hemolytic milk streptococci of the lactic acid type referred to above, usually will kill or cause lesions in rabbits in doses of from 2 to 3 c.c. in 1,000 gm. animals. There are exceptions to this, some strains requiring larger doses. On the whole, however, one may say that the virulence of hemolytic streptococci for rabbits is decidedly higher than that of the green producing streptococci. Highly virulent (as determined by rabbit injection) strains of streptococci may be obtained from normal persons, and less virulent strains at times from severe human infections; but in general the more virulent strains for animals come from virulent human infections. By animal passage it is possible to enhance the virulence of hemolytic streptococci to some extent, though the range is decidedly limited. I have never observed it consistently higher than 0.5 c.c. of serum broth culture per 1,000 gm. rabbit. The organism is therefore in this respect decidedly different from the pneumococcus. On artificial mediums, including blood agar, the virulence decreases materially though slowly. My hemolytic streptococci from the milk epidemic of 1910, some of which then killed rabbits in doses of 0.5 c.c., will not at present kill in doses of 4 or 5 c.c. intravenously. For mice, streptococci appear to be more highly virulent, and may by several passages acquire aggressive properties for this animal comparable to pneumococci.

ANTIBODIES

As to antibody formation in animals and in man it may be stated from the work of Hektoen, Tunnicliff, Ruediger and others that definte specific opsonins appear both after various streptococcal diseases and after artificial inoculation with dead bacteria. These appear to be the most important antibodies formed, and so far as is known the self limitation of hemolytic streptococcal infections probably depends on them. Specific agglutinins have been shown by various observers to appear; but they are inconstant, low in titer, and more or less specific for the homologous strain. Smith and Brown[3] and Krumwiede[7] have found them useful in identifying strains suspected of causing epidemics of sore throat. Kinsella[8] and others have noted the production of complement fixing bodies in immunized animals, and use this for purposes of classification. On this basis the hemolytic streptococci from man seem to form a homogenous group. Antibodies for streptolysin and a possible toxic filtrate have already been referred to.

IMMUNITY AND RESISTANCE

Many animals, as the guinea-pig, the rat and the bird, are naturally more or less immune to streptococci. Others, as man, the horse, the cow, the mouse and the rabbit, are more susceptible to both natural and experimental infection. Acquired immunity following a natural streptococcus infection, if it occurs at all, is slight and of short duration. Many diseases caused by streptococci, as erysipelas, pneumonia and sore throat, are prone to second attacks, though the attacks are usually separated by periods of months or at least of several weeks. Experimentally, animals may be immunized. Moore[9] has shown that rabbits may be immunized against homologous strains by prophylactic injections of dead hemolytic streptococci. This immunity persisted over forty days, at least in one instance, and seemed to be dependent on the production of opsonins.[10] Concentrated antistreptococcus serum did not exhibit any protective value. The antistreptococcus serums of Marmorek, Aronsen, Moser and of many others that have come on the market in recent years have been distinctly disappointing for both prophylactic and curative purposes.

The aggressive properties of the streptococcus, and the immunizing and resisting powers of the patient, are no doubt intimately related, making it extremely difficult to analyze satisfactorily the various factors involved. The differences between the aggressive or virulent property of strains of hemolytic streptococci are not great, at least according to what our various methods of study reveal. So, too, immunity reactions on the part of the host after either natural or experimental infection are not especially intense or active. There is little doubt that these factors, however, do play an important rôle in determining the course of infection. To illustrate: I observed a small streptococcus infection on the finger of a person following a necropsy. It caused a rise in temperature of 2 or 3 degrees, a leukocytosis of 12,000, malaise, headache and a chilly sensation. A small drop of pus was expressed through an opening near the finger nail, and in thirty minutes the temperature had returned to normal and all distress was relieved. In the pus were a moderate number of hemolytic streptococci. At the same time I was observing a man, apparently feeling little worse and who later recovered, with a streptococcus empyema and more than a liter of pus in his thorax, every smear of which revealed hundreds of streptococci. In morphology, in culture, and in virulence for animals, the hemolytic streptococci from these two cases could not be distinguished; and neither strain could be distinguished from certain hemolytic streptococci cultivated from normal tonsils.

PATHOGENESIS

For Animals.—Many animals are prone to natural infections with hemolytic streptococci. The horse seems peculiarly susceptible, and a variety of infections both acute and chronic result. Mathers,[11] two years ago, studied the interesting disease equine influenza, or shipping fever, in horses, and found the cause to be a hemolytic streptococcus. Various organs of the body, but especially the respiratory passages, were attacked. The streptococcus was culturally and morphologically quite like the hemolytic streptococcus commonly found in human disease. However, there is no evidence that it is dangerous or virulent for man, and no causal relation between epidemics in horses with epidemics or even individual cases in man could be detected.

In cows, streptococcus infections, especially of the udder, are common. Many are caused by hemolytic streptococci, an occasional strain of which is evidently of human origin. These streptococci may be virulent for man, and, being disseminated through the milk, may be responsible for epidemics of streptococcus sore throats, several of which have now been observed in the United States and many more in Europe. Experimentally, it has been shown[12] that hemolytic streptococci of human origin, when planted on the teat, especially if it has been abraded, may ascend the ducts and cause a long enduring infection in the udder of the cow. The udder may show extremely little evidence of disease, and the milk grossly may be quite normal. Microscopically, however, the leukocytes are greatly increased, and the virulent streptococci are shed in the milk in large numbers for weeks or months. Apparently only a few of the hemolytic streptococci found in milk and causing mastitis in cows are dangerous to man. Jones[13] has compared twenty-eight strains of hemolytic streptococci from the udders of infected cows, and has found that though they are typical hemolyzers, they are of low virulence for rabbits. All except three were specifically agglutinated by antiserum prepared from one strain. Three strains of hemolytic streptococci of human origin were not agglutinated by this antiserum.

For Man.—The pathogenesis of hemolytic streptococci for man forms one of the most important chapters in human medicine, since every department and specialty meet and must handle this problem constantly and from various standpoints. Of the skin diseases, erysipelas is one of the definite infections caused by this organism. The streptococcus of erysipelas has been considered specific for this disease. We do not yet know that it is not, but experimentally erysipelas has been produced by streptococci from other sources, and erysipelas streptococci have long been known to cause puerperal sepsis. Hemolytic streptococci cause or are often associated with other lesions of the skin.

Sore throat, sporadic and epidemic in character, is commonly caused by hemolytic streptococci. The epi-

[8] Kinsella: J. Exper. Med. **28**: 169, 1918.

[9] Moore: Jour. Infect. Dis. **15**: 215, 1914.

[10] This may be considered as a theoretical basis for prophylactic vaccination in man against hemolytic streptococci. However, the liability to second attacks of streptococcus infections in general indicates that if any immunity at all is established it is probably of short duration—a few weeks at most.

Since there are several hemolytic streptococci, I shall not attempt to discuss them all, but will limit myself to those streptococci that are pathogenic for man, or at least potentially so, and will refer to them as pathogenic hemolytic streptococci, understanding that here are included several different varieties, though possessing many important properties in common. They are the organisms commonly referred to as *S. hemolyticus* and roughly also as *S. pyogenes*.

Morphologically, they are spherical or slightly oval, and form definite chains, often quite long, though in the tissues if rapidly multiplying they are frequently seen in pairs or short chains. In the chain, pairing is noted often, though not to the extent seen in pneumococci or in the green streptococci. Their reaction on sugars is varied and, as we have already seen, on this basis they may be classified. Many strains ferment lactose and salicin; a few ferment mannite.

POISONOUS PRODUCTS

Our knowledge of their poisonous products is meager, though no doubt they produce highly toxic bodies. Their hemolytic activity is caused by a hemolysin called streptolysin, and is produced both in vivo and in vitro. According to Ruediger,[5] who studied this substance in detail, it has the structure of a true soluble toxin with a haptophore and a toxophore group. On injection into animals, it gives rise to a specific antibody (Besredka). In severe infections, hemolysis may occur in the vessels in animals and in man with resulting hemoglobinemia. Streptolysin, however, does not appear to be the most important poison produced, since it is not highly toxic and its production does not parallel the intensity of the infection. Nor are the important lesions produced of such a nature as to lead one to think they are caused by the hemolysin. Hemolytic streptococci are not dangerous primarily because they are hemolytic. Some nonhemolytic streptococci are far more dangerous than the hemolytic varieties.

Recently Clark and Felton[6] reported that by growing hemolytic streptococci (isolated from Army camp bronchopneumonias) in rabbit's blood diluted with Locke's solution they obtained a filtrable toxic product which kills rabbits at times in doses of 0.5 c.c. per kilogram intravenously. Its formation is in some way dependent on hemoglobin, but the poison is nonhemolytic in vivo and in vitro. They report that its introduction into a rabbit will immunize both against the poison and against living streptococci. I am not aware that this work has been confirmed. If repeated successfully, it will make an important step in our knowledge of these organisms.

Filtrates of old cultures are only very slightly toxic, and the dead bodies of streptococci either highly or slightly virulent, killed in various ways, can be injected into animals and man in relatively large doses without marked toxic symptoms. They behave in this respect quite like numerous other pathogenic bacteria whose poison lies closely bound with the bacterial cell and to which we apply the term "endotoxin." Practically nothing is known about it.

VIRULENCE

The aggressive and invasive properties of streptococci deserve first consideration, for under certain conditions no other organism known manifests such varied and extensive activities. Aggressins in the sense of Bail have been described, but how they act is not certain. I am inclined more and more to regard the existence of a capsular substance about these streptococci as of considerable, perhaps fundamental, significance. We know very well the virulence of *Streptococcus* or *Pneumococcus mucosus*. I have tested many strains, and all, even those of relatively low virulence, if injected into animals, can be made to reveal a capsule. The highly virulent streptococci, those, for example, from milk epidemics, readily show a capsule in sputum, exudate or blood. Generally, the more virulent the organism, the more distinct is the capsule and the less susceptible are the cocci to phagocytosis. In the streptopneumococcus group, many facts point to a parallelism between capsule substance and virulence.

The virulence of hemolytic streptococci seems to vary markedly for man. This property is so intimately bound up with invasive properties and with the resistance and immunity of the host that analysis of this factor is difficult. In the human being, marked differences in the intensity of infection are commonly observed, though caused by streptococci which, when isolated, are apparently alike, and on animal inoculation show little difference in virulence. To sum up many observations on the virulence of different strains for rabbits, one practically never encounters a hemolytic streptococcus that will kill a 1,000 gm. rabbit in doses of less than 0.5 c.c. of a twenty-four hour serum broth culture intravenously. Usually the highly virulent human strains require larger doses (1 c.c.) to kill or to cause joint and other lesions in rabbits. Guinea-pigs are distinctly less susceptible than rabbits. On the other hand, hemolytic streptococci, with the exception of the hemolytic milk streptococci of the lactic acid type referred to above, usually will kill or cause lesions in rabbits in doses of from 2 to 3 c.c. in 1,000 gm. animals. There are exceptions to this, some strains requiring larger doses. On the whole, however, one may say that the virulence of hemolytic streptococci for rabbits is decidedly higher than that of the green producing streptococci. Highly virulent (as determined by rabbit injection) strains of streptococci may be obtained from normal persons, and less virulent strains at times from severe human infections; but in general the more virulent strains for animals come from virulent human infections. By animal passage it is possible to enhance the virulence of hemolytic streptococci to some extent, though the range is decidedly limited. I have never observed it consistently higher than 0.5 c.c. of serum broth culture per 1,000 gm. rabbit. The organism is therefore in this respect decidedly different from the pneumococcus. On artificial mediums, including blood agar, the virulence decreases materially though slowly. My hemolytic streptococci from the milk epidemic of 1910, some of which then killed rabbits in doses of 0.5 c.c., will not at present kill in doses of 4 or 5 c.c. intravenously. For mice, streptococci appear to be more highly virulent, and may by several passages acquire aggressive properties for this animal comparable to pneumococci.

ANTIBODIES

As to antibody formation in animals and in man it may be stated from the work of Hektoen, Tunnicliff, Ruediger and others that defnite specific opsonins appear both after various streptococcal diseases and being, possibly soon or during the coming winter acquire properties that will enable them to cause an epidemic of primary streptococcal pneumonia comparable to those of a year ago? I am not aware that any of the now recurring epidemics of influenza are of this character; but we should be on our guard against such an event.

DISTRIBUTION OF HEMOLYTIC STREPTOCOCCI IN THE HUMAN BODY

In 1912, in studying the bacteriology of the tonsils from various diseases, including arthritis, nephritis and myocarditis, I[20] was struck with the common occurrence of typical hemolytic streptococci in the crypts, often in pure culture, whereas on the surface of the same tonsils they were often few or absent, while the green-producing cocci predominated. In forty-eight cases of the foregoing diseases the hemolytic streptococcus was predominant or abundant in forty-five, or 94 per cent. In a series of sixty-one pairs of tonsils, which were extirpated mostly from children for various reasons, chiefly hypertrophy, many appeared quite normal, and hemolytic streptococci were found practically as often, namely, in fifty-five, or 90 per cent. In subsequent work the cultivation[21] of numerous tonsils from a variety of diseases has convinced me that the crypts of the tonsils are in almost all cases the habitat of many hemolytic streptococci, often almost pure. Pilot[22] has recently investigated this matter and carefully compared the tonsillar crypt flora with throat swab and tonsil surface cultures. Briefly, in 100 cases of ordinary hypertrophy without inflammation, the pharynx was positive for hemolytic streptococci in 43 per cent. and the tonsil surface in 61 per cent., and in these the hemolytic colonies numbered less than 10 per cent. of the total number of colonies. In the crypts of the same tonsils after extirpation the hemolytic streptococci were found in 97 per cent of the tonsils, and in most of these were greatly predominant. Furthermore, Pilot found that in twenty-four normal persons, cultures from the surface of tonsils revealed hemolytic streptococci in 58 per cent., usually not predominant. In nineteen persons without tonsils, cultures from the pharynx and tonsillar region yielded hemolytic streptococci in only three, or 15 per cent. The recent work of Nichols and Bryan[23] in the United States Army is quite in accord with these data and indicates that the crypts of the tonsils are a common habitat for hemolytic streptococci.

I will call attention also to the very common occurrence of the actinomyces-like granules[24] in the tonsils of nearly every one at some time. In these granules, hemolytic streptococci, as well as nonhemolytic streptococci with rather marked anaerobic properties, appear sometimes in large numbers and in a high proportion of instances.

The hemolytic streptococci found in tonsils and in throats of apparently normal persons seem to be typical in every respect. For rabbits many of them are distinctly pathogenic, as pathogenic as many strains from sore throats or from abscesses. According to Holman's classification, they would fall chiefly into the *S. pyogenes* and *S. anginosus* groups.

I know of no other anatomic structure or location in the body that so consistently harbors hemolytic streptococci as do the tonsillar crypts. In the nose they are rare. I have never found them persistently present in a normal nasal mucosa, and their presence there means almost surely an infection, usually an infected sinus. In the pharynx of normal persons, as we have seen, they are found roughly in between 50 and 60 per cent., but in the absence of inflammation not in large numbers. I raise the question as to the possibility of the tonsil crypts being the chief feeding focus of hemolytic streptococci for the throat and the respiratory passages. In a few cases in which I have examined adenoids I am not convinced that they are an important habitat for streptococci, though they may be found in moderate numbers in the hypertrophied tissues. About the mouth and teeth, infected foci may commonly be feeders of streptococci for the throat; but the normal gums do not harbor them in large numbers. The skin of persons who bathe regularly rarely harbors hemolytic streptococci. Schachter[25] found no hemolytic streptococci on the bodies of thirty-eight clean persons; whereas he isolated hemolytic streptococci from the skin eight times from eighty-nine filthy persons, usually from the hairy parts of the body. They were not numerous, but were typical and virulent for rabbits. The source of such organisms may very well be the buccal secretions. Hemolytic streptococci, when placed experimentally on the human skin, usually disappear in a few hours and are readily removed by washing.

The gastro-intestinal tract seems to be quite free from hemolytic streptococci, at least normally. I have recently had occasion to study this point both experimentally and in man, being induced to do this to determine the fate of the hemolytic streptococci that are swallowed almost constantly by normal persons and by those infected with the numerous streptococcal respiratory diseases. Examination of fifty-three stools from a series of persons, many of whom were known to have hemolytic streptococci in their throats, did not reveal a single colony in any case. Stools from several scarlet fever patients showed no hemolytic streptococci. Three rabbits were given by stomach tube from 10 to 20 c.c. of a culture of virulent hemolytic streptococci every day or every other day for one month. The rabbits' stools were examined from time to time, and with one exception were always negative for these streptococci. The stomach and intestinal contents of such rabbits and also rabbits suffering with streptococcus arthritis were likewise invariably free. Hemolytic streptococci are very sensitive to the acids of the stomach or to free hydrochloric acid. When placed in the stomach contents of human beings or rabbits even in large numbers, they are all dead in from two to five minutes. Strains vary somewhat, but generally they are killed in two hundred and fifty-sixth normal (0.012 per cent.) hydrochloric acid in two minutes. They will live, however, in the intestinal contents of feces, at least for several days. From the foregoing experiments and observations we may conclude, I think, that ordinarily hemolytic streptococci, though swallowed in large numbers, are quickly destroyed in the gastro-intestinal tract, and that the feces from infected persons are not a source of danger in spreading the infection. Some preliminary work in the laboratory on the appendix indicates that it is not a common habitat for hemolytic streptococci.

RÔLE OF HEMOLYTIC STREPTOCOCCI AS PRIMARY AND SECONDARY INVADERS

Summing up these observations on the distribution of hemolytic streptococci, the facts point strongly to the crypts of the tonsils as being the main and in a sense a normal habitat of these organisms in the human body. Perhaps they are as normal to the tonsil crypts as is *Streptococcus viridans* to the buccal mucosa, *Staphylococcus albus* to the skin, or the colon bacillus to the intestine. From here they may be disseminated to adjacent tissues, ready possibly to take advantage of certain conditions, especially diseases of the respiratory tract, and give rise to secondary infections of a most serious nature.

The question arises as to whether or not persons are commonly or usually infected with their own hemolytic streptococci, or are the invading streptococci in infected persons of foreign origin? No doubt the latter statement is often true, as seems clearly proved in the case of sore throat epidemics of milk origin. Furthermore, many facts point to the common dissemination of streptococci by means of droplet infection. The route of infection is not so clear, however, in secondary streptococcus infections following other diseases. In the common terminal infections so often due to this organism there is little doubt that the individual is killed by his own streptococci.[26] It has been pointed out that such streptococci are as virulent as epidemic streptococci for man, especially after growing in the body for a time. It would seem reasonable to assume, as has been assumed by some in connection with the streptococcus empyemas of last year, that individuals are being infected from time to time with their own streptococci, especially following the contagious diseases, and that by this process the streptococci become more and more virulent and aggressive, reaching a point ultimately at which the small doses contained in infected droplets or in other vehicles are sufficient to transmit the disease to a normal person. Thus a secondary invader may become transformed into a dangerous primary infective agent.

Nonworkers Should Hibernate.—A correspondent in the *British Medical Journal* (February 26) advocates as a means of food saving a modified hibernation on the part of nonworkers. He says that, roughly, five sixths of food values go to producing and maintaining animal heat, and one sixth to the production of physical and mental energy. Of every 100 calories of heat produced within the body 80.1 per cent. is lost by radiation and conduction; 14.7 by evaporation; 2.6 per cent. in heating food and drink consumed, and 2.6 per cent. in heating inspired air. Lying in bed till late in the day by nonworkers, he says, will clearly reduce the heat loss and output of energy, with consequent saving in food requirement. He therefore says the idle poor, the rich, infirm and insane persons should be compelled to remain in bed, warm and at rest till noon daily.

THE IMPORTANCE OF THE LOUSE PROBLEM *

HARRY PLOTZ, M.D. (Brooklyn)
Major, M. C., U. S. Army
WASHINGTON, D. C.

The demobilization of armies is usually associated with the introduction of epidemic diseases into civil communities. There is great possibility of louse-borne diseases gaining entrance into the United States unless necessary measures are taken to exclude them. The question as to whether epidemic influenza could have been excluded from this country remains an open one; but it can be said with a certain degree of certainty, that with the application of proper measures, epidemic typhus fever, trench fever and relapsing fever can be excluded. In view of the fact that the louse has spread more disease in the present war than all the other insects combined, its importance as a disease carrier can be appreciated. It is important, therefore, that proper facilities be provided to delouse all returning troops, that the public health authorities provide measures for the delousing of immigrants, and that physicians be on the alert for the possible occurrence of louse-borne diseases, leading to the early isolation of those affected.

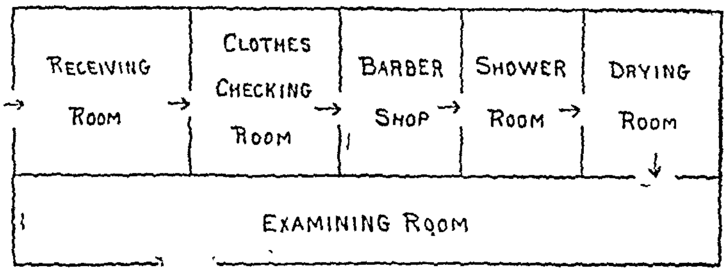

Fig. 1.—Scheme for delousing.

Vermin infestation is now prevalent throughout Europe, the annoyance of the "cootie" being well known to all American soldiers. Coincident with this widespread vermin infestation exists the impoverishment of most European peoples. These conditions usually precede a typhus fever epidemic. This fact is often related in the history of typhus fever. Epidemic typhus fever has already made its appearance in European countries, and with the advent of winter, when the disease is most common, we have much to fear from a general typhus fever epidemic. The Allied troops are coming more and more in contact with the Russian and Balkan peoples, and the spread of this disease from army to army and then from country to country need be anticipated. For these reasons it is believed that due consideration should be given this problem, and proper measures be employed to exclude these diseases from the United States. It is important to point out that endemic typhus fever (Brill's disease) is a disease not uncommon in this country; and with the introduction of vermin, we may fear a greater number of cases and a possible increase in its virulence.

The eradication of vermin infestation calls for strict adherence to a certain definite plan of treatment. It has been said that vermin infestation in European armies started from a few infested individuals, and owing to the close association of the troops, the infestation rapidly spread. The escape of one vermin-infested individual into a community may cause considerable infestation. A vermin-infested man, then, should be regarded in the same light in which one regards a meningococcus carrier: he is a danger to the community until his condition is cleared up.

---

* From the Division of Sanitation, Medical Department, U. S. Army.

FUNDAMENTAL PRINCIPLES

In order that the best results may be obtained, there are certain fundamental principles regarding the subject of delousing that must be taken into consideration.

1. The clothes louse (*Pediculus humanus-corporis*) transmits typhus fever, trench fever and relapsing fever. These diseases are not transmitted by the bite of the louse but by a virus which is contained in the excreta. This virus gains entrance through the puncture wound made by the louse while sucking, or is scratched in by the infested individual. Therefore, a method which destroys only the lice and eggs without causing the destruction of the virus in the excreta is not sufficient. Delousing, then, should be defined as that process which destroyes lice and their eggs and the virus concerned in the transmission of disease.

2. Various methods have been recommended for delousing, such as hydrocyanic acid gas, chloropicrin, and various insecticides and heat appliances. It is to be noted that the virus of relapsing fever is a spirochete, while that of typhus fever is a bacillus. As these gases and insecticides are not bactericidal, they cannot be regarded as perfect delousing agents. In all instances in which heat is used, a high enough temperature must be employed to destroy the virus as well as lice and eggs. Steam has been found to be the best delousing agent.

3. All persons coming from a vermin-infested area should be regarded as if they were vermin infested. Examination for vermin in large bodies of men, even in the hands of experts, is of little value. A great deal of time is consumed in the examination, and the final result is of little use.

4. Clothes lice may lay their eggs on the hair of the head and of the axillary and pubic regions. This must be taken into consideration when treating this condition.

Clothes lice should be treated by sterilizing all clothing by exposure to steam under pressure for thirty minutes followed by ten minutes in a vacuum. The clothes then come out dry. If shrinkage of woolen materials result, the disinfector is not properly operated. Shrinkage of woolen materials is due to combined moisture and high temperature; therefore, if the moisture is kept at a minimum and the temperature at a point sufficient to sterilize, this will not occur. In no instance should leather material (such as shoes, puttees and hat) or rubber, celluloid material or money be sterilized. The occurrence of vermin in these materials is rare.

ARMY PLAN

The Army proposes to handle the problem in this manner: All troops will be detained at foreign ports for a period of two weeks, during which time persons with infectious and epidemic diseases will be isolated and universal delousing will be practiced before embarking. Delousing will be practiced on transports when necessary. All soldiers on transports will be instructed to devote fifteen minutes each day to the search for vermin in their clothing. Universal delousing will be again practiced at debarkation camps in the United States. This will serve as a check on the first delousing.

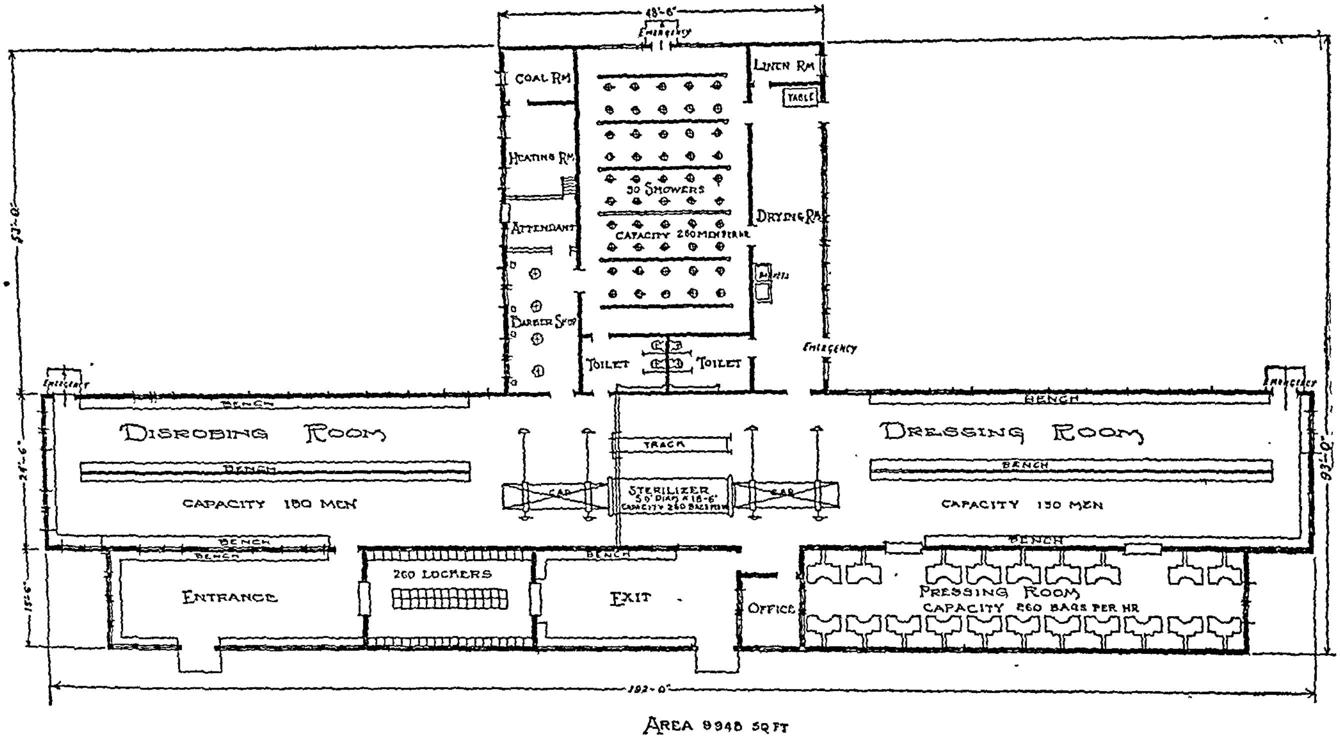

Fig. 2.—Plan of delousing plant.

AN EFFICIENT DELOUSING PLANT

All sick and wounded will be deloused at the debarkation hospital. An efficient method would be to have the delousing room in association with the receiving ward. The following plan is suggested for this purpose. With this method vermin infestation would be prevented from being carried to the wards.

In order that the greatest number of men may be handled in the shortest period of time, it is important to have a rapidly functioning delousing plant. According to the plan here proposed, 260 soldiers and all their equipment can be deloused every hour. According to this plan the man enters with his barrack bag containing all his clothing. The leather materials, rubber, celluloid materials and money are passed in at the locker room. The man receives two numbered tags corresponding to the number of the locker, and then proceeds to the disrobing room with his barrack bag. All his clothing is placed in the bag, which is tied and numbered with one of the tags, the man retaining the remaining tag. The bag is then placed in the carriage, which is pushed into the steam sterilizer. The sterilizer is 18½ feet long by 5 feet in diameter and is provided with two cars and transfer tracks, so that one car will be loading or unloading while the other is in the sterilizer.

The soldier then proceeds to the hair-cutting room. Before entering, he is inspected for vermin and nits. If vermin and nits are found in the hair of the head, axillary or pubic region, he is passed into the barber shop. If none are found, he passes into the shower room. In the barber shop the hair is cropped with an electric hair-cutting machine. The axillary and pubic hair can be shaved in this room. Following this he enters a shower room, where a bath with liquid soap and warm water is obtained. The soap used is a kerosene soap mixture. A drying room follows, a table being provided for the clean towels and a receptacle to receive the soiled ones.

Provision is made in this plan for a pressing room, as the clothing is wrinkled following steam sterilization. The pressing of garments, however, would somewhat retard the process. The leather material, etc., is reclaimed at the locker room. The floor of this building is made of concrete. Two toilets are provided, one for the dirty men and one for the clean men. All attendants wear the louse-proof suit, which is a one-piece garment covering the shoes and tied about the neck.

With an arrangement such as this, when universal delousing is practiced, there should be no danger of vermin infestation or louse-borne diseases gaining entrance into the United States.

INTESTINAL PARASITES DURING A YEAR AT THE WALTER REED GENERAL HOSPITAL *

M. W. LYON, Jr., M.D.
Captain, M. C., U. S. Army
WASHINGTON, D. C.

During the year October, 1917, to October, 1918, there were examined at the laboratory of the Walter Reed General Hospital 477 samples of feces for intestinal parasites. In nearly every instance the samples were submitted because the patient had shown some evident or obscure reason for suspecting the presence of intestinal animal parasites, although there are included a number of samples that were sent for examination for typhoid or dysentery bacilli. The 477 stools came from 163 individuals, seventy-two of whom, or 44 per cent., were found to harbor one or more kinds of parasites, while in ninety-one persons, or 56 per cent., no parasites were found.

With the exception of *Endameba histolytica*, none of these cases of intestinal parasites can be said to possess much medical interest. Their presence is one of greater zoological than medical interest. Next to the ameba infections the hookworm cases are of most interest. Most of these were very light infections, but they are an indication of how widely scattered this parasite has probably become during the formation of the Army.

The method practiced in looking for protozoan parasites is to place a drop of the feces, either plain or mixed with a little water or salt solution, on a slide and press it out with a cover glass. No attempt is made to concentrate cysts. In searching for ova or embryos a considerable portion of the stool is emulsified with water, usually by pouring water into the container in which it is sent to the laboratory. The liquid material is then poured through two thicknesses of gauze into a urine sedimentation glass. After a distinct sediment has formed in the point of the glass, the brown supernatant water is poured off. More water is then roughly added so that the sediment is thoroughly stirred up, and it is allowed to settle again. This washing is repeated several times until the supernatant water is essentially clear. After the final sedimentation, about 0.25 c.c. of the upper layers of the sediment is spread on a slide without a cover glass and search made with the low powers of the microscope, a mechanical stage being used. The spread occupies most of the slide, and by the use of a wax-penciled border is kept from running over its edges. The chief advantage in the washing and sedimentation is that innumerable small particles, mainly bacteria, are got rid of, and a very clear sediment is left to examine. The washing may appear time consuming, but it takes only a moment to pour off and fill up again, and while the settling is taking place other things can be attended to. Examination of one spread slide is considered sufficient to establish the presence of ova. In a few cases, however, an especially enthusiastic searcher has found an ovum or an embryo in examining a second spread which had not been found on the first.

Hookworm, *Necator americanus,* was found most frequently, occurring in 34.2 per cent. of the parasites and 17.2 per cent. of the persons examined. The number of worms was always small. The largest number recovered from complete stools after hookworm treatment was seventy-one and the smallest two. Its presence often caused a slight eosinophilia. The first case found was in a patient whose blood, on being examined for malaria parasites, showed so many eosinophils that a stool for examination was requested. The farthest north from which the hookworm cases came was Virginia and Tennessee. Hookworm ova were found alone twenty-three times; with *Strongyloides* embryos twice; with *Endameba coli* twice; with *Ascaris* and *Trichuris* twice, and with *E. coli, Trichuris* and *Trichomonas* once.

Strongyloides, occurring in 4.3 per cent of the persons examined and 8.5 per cent of the parasites, was found alone five times and twice with *Necator*. With two exceptions they were not present in large numbers. In one of these they were the only parasite present, and in the other they were with the second heaviest hookworm infestation, and both were in patients in the tuberculosis ward. In the case occurring with hookworm, successful treatment for the latter failed to have any effect in reducing the number of *Strongyloides* embryos.

The five *Taenia saginata* cases were not diagnosed in the first instance by the laboratory, but having been found elsewhere, were sent into the hospital for treatment.

---

* From the Laboratory Service of the Walter Reed General Hospital.

The three *Trichuris* cases were light infections. In one of the cases in which it was the only parasite present, the host came from Brooklyn, while in the other two cases the patients were from the Southern states.

Of the four *Ascaris* infestations, two were present alone in small numbers and two occurred with both *Necator* and *Endameba coli;* once with *E. histolytica,* thirty-four worms were recovered. It was one of the few cases in which intestinal helminthiasis appeared to be the only pathologic condition in a patient.

The two cases of infestation with dwarf tapeworm, *Hymenolepis* occurred without other parasites being present.

The single case of *Oxyuris* occurred in a nurse.

Endameba coli was present in seventeen of the persons examined, and next to hookworm was the most frequent parasite, occurring in 10.4 per cent. of the persons and 20.6 per cent. parasites. It occurred alone twelve times, with *E. histolytica* once, with *Necator* twice; with *Trichuris, Necator,* and *Trichomonas* once, and with *Trichomonas* once.

Endameba histolytica was found in ten individuals, 6.1 per cent, and 12.2 per cent among the parasites. The patients having it were either from the Southern states or had had tropical service. It occurred alone eight times; with *E. coli* once, and with *Trichomonas* once. None of the cases showed any manifestation of the infection outside of the intestine. One case was of particular interest. The patient was an especially well built person and was receiving a third course of emetin hypodermically, as two previous courses had failed to destroy the amebas. Although apparently perfectly well during the previous day and able to be up and about, he went into a state of collapse one night. Stimulants failed to revive him, and he died the next morning. Necropsy revealed no abnormalities other than venous congestion and a rather extreme dilatation of the right side of the heart. No evidence of the amebic infection was present. There is little doubt that death was due to the specific action of the emetin. In its symptoms and pathology this case is quite similar to the two fatalities described by Johnson and Murphy.[1]

FREQUENCY WITH WHICH PARASITES WERE FOUND

Name	Number of Cases	Percentage of Frequency of Parasites	Percentage of Persons
Necator americanus	28	34.2	17.2
Endameba coli	17	20.6	10.4
Endameba histolytica	10	12.2	6.1
Strongyloides stercoralis	7	8.5	4.3
Taenia saginata	5	6.1	3.1
Ascaris lumbricoides	4	4.9	2.5
Trichuris trichiura	3	3.7	1.8
Trichomonas intestinalis	3	3.7	1.8
Giardia intestinalis	2	2.4	1.2
Hymenolepis nana	2	2.4	1.2
Oxyuris vermicularis	1	1.2	0.6

Only two cases of *Giardia* infections were noticed. In one, numerous cysts were present in the stool. The organisms were then obtained in active form by securing intestinal contents through a duodenal tube. The other case was a mild infection, and the few cysts in the stool escaped observation until after the active parasites had been seen in rather large numbers in bile from the duodenum, the bile having been obtained for examination for typhoid bacilli in a case of a suspected typhoid carrier. Undoubtedly many other cases of *Giardia* infection escaped observation.

Trichomonas was observed three times, always in conjunction with other parasites, once with *Trichuris, Necator* and *Endameba coli;* once with *E. histolytica* and once with *E. coli.*

In the table are shown the number of individuals in which the various parasites were found, and the percentage of frequency of each parasite and its percentage of occurrence among the persons whose stools were examined.

THE DIAGNOSIS OF MITRAL REGURGITATION (VALVULITIS)

MARCUS A. ROTHSCHILD, M.D.
Major, M. C., U. S. Army
NEW YORK

Mitral regurgitation, which has been assumed to be the easiest of all valvular diseases to recognize, is, in my experience, the most difficult. It is essential that one define mitral regurgitation on a pathologic basis. Mitral valvular disease in this sense is assumed to consist pathologically of a true valvulitis.

The presence of a systolic murmur at the apex, transmitted to the axilla, has quite generally been regarded as evidence of mitral valvular disease. It is my opinion that entirely too much emphasis has been laid on the presence of a systolic murmur. The large number of adventitious sounds heard in examining recruits has been a matter of surprise. Deviations of the cardiac mechanism from the presumed normal are almost the rule. Systolic, apical or basic murmurs are heard in at least 50 per cent. of all men examined, especially immediately after exercise. The intensity of these apical murmurs varies greatly; usually they are soft, with only short, lateral areas of transmission. At other times, however, they are loud and rough, transmitted to the axilla and angle of the scapula, only to disappear with the decrease in the heart rate. The basic systolic murmurs, because of one's previous training and habit of thought, are usually disregarded by examiners. The apical murmurs, however, are regarded with suspicion and are not infrequently interpreted as of serious import.

In the examination of a large number of young soldiers between the ages of 21 and 31, approximately 3 per cent. are rejected for full military service because of cardiovascular conditions. It is interesting to compare the causes of rejections as submitted by various examiners. Mitral regurgitation may occupy the most prominent position or the least prominent, depending on the interpretation of the physical signs by the examiner. It is necessary that certain criteria be established in order to standardize the work. This is illustrated by the rejections of a board consisting of six medical officers, working in the same camp at two widely separate stations. At Station 1, 4,217 men were examined, and 144, or 3.4 per cent., were rejected. At Station 2, 3,777 men were examined, and 118, or 3.1 per cent., rejected. At Station 1, functional cardiovascular disorders composed 74.3 per cent. of the total rejections, while at Station 2 they composed only 49.6 per cent. This may be explained by the fact that at Station 1 we were more rigid in our criteria in diagnosing mitral regurgitation. This is evidenced by the fact that Board 1 diagnosed only seven cases of mitral regurgitation, while Board 2 diagnosed forty-six.

---

[1] Johnson, H. H., and Murphy, J. A.: The Toxic Effect of Hydrochloride, Mil. Surgeon 40: 58-70, 1917.

In the examination of 10,000 limited service men at Syracuse Recruit Camp, careful records were kept of abnormalities. Six hundred and sixteen soldiers, or 6.16 per cent., were placed in limited service because of neurocirculatory asthenia or functional cardiovascular disorder. The diagnosis of mitral regurgitation was made in thirty-three instances, or 0.33 per cent. In 191 recruits, 1.9 per cent. systolic, apical murmurs were noted. Not all systolic, apical murmurs were recorded, but only those of such a degree of intensity as possibly might be interpreted by some as of significance. In thirty other soldiers a systolic murmur was heard at the apex, which, in conjunction with other symptoms and physical signs, caused us to limit their service. This group is an intermediate one and is most difficult of interpretation. Systolic murmurs were recorded in 870 cases, or 8.7 per cent., and the diagnosis of mitral regurgitation was made definitely in only thirty-three cases, or 0.33 per cent. of the total examined. However, in contrast with these figures, some examiners report that from 15 to 60 per cent. of their rejections were for mitral valvular disease.

We have used these criteria for the diagnosis of mitral valvular disease: (1) cardiac hypertrophy; (2) a systolic, apical murmur, and (3) a definite history of one or more attacks of acute articular rheumatism (not growing pains or tonsillitis).

In my opinion, it is necessary, in order to make the diagnosis of mitral regurgitation, to have the first and second or the third and second of these criteria. The presence of definite hypertrophy always means heart disease. In the absence of cardiac hypertrophy, and even in the absence of symptoms, a systolic, apical murmur and a definite history of one or more attacks of acute articular rheumatism should be considered significant. Using these criteria, we were able to label only thirty-three, or 3.8 per cent., of the 870 cases with systolic murmurs as mitral regurgitation (valvulitis).

In the criteria used for the diagnosis of mitral regurgitation, such physical signs as an accentuated or split pulmonic second sound were purposely omitted. This physical sign per se is, in my experience, of practically no value. It is a fairly constant phenomenon in the overacting heart and is normally found in young adults. Abdominal pulsation of the type corresponding to the contractions of the right ventricle is also of no differential value. The character of the pulse, or the presence of irregularities, such as ventricular premature beats, is of even less significance. The intensity or the propagation of the murmur is at best a sign of doubtful value. It must be admitted that, given a soldier with no hypertrophy, no definite history of acute articular rheumatism and no symptoms, but with a loud, musical, systolic murmur at the apex transmitted to the axilla and angle of the scapula, because of one's previous training and habit of thought, it is extremely difficult to disregard this murmur absolutely. The plea is made, however, not to lay too much emphasis on this murmur, especially if there is tachycardia. It is my opinion that this murmur signifies more in a slow acting heart. I have observed murmurs of this kind disappear within a few hours. Only by following these cases for a period of years can sufficient data be accumulated to formulate a definite prognosis.

The differential diagnosis of mitral valvulitis (regurgitation) must be made from the following conditions: (1) functional cardiovascular disorder, disordered action of the heart, "irritable heart of soldiers," neurocirculatory asthenia; (2) accidental systolic, apical murmurs.

The differential diagnosis from functional cardiovascular disorders is not especially difficult. The absence of cardiac hypertrophy plus the accompanying physical signs of functional cardiovascular disorder, independent of the cardiac manifestations, make the differential diagnosis fairly simple. The intensity and propagation of these murmurs may not differ in any way from the type of murmur seen in true valvulitis. However, the other symptoms and signs of neurocirculatory asthenia are absent in the cases of true, organic, mitral valvulitis. Occasionally, a case of mitral valvulitis may also have a neurocirculatory asthenia complex. In this instance, the diagnosis of the combination is extremely difficult. After excluding the neurocirculatory asthenia group, we are left with a group of cases with no cardiac hypertrophy, but with the systolic, apical murmurs. This is the group that offers the greatest difficulty in proper interpretation. It is the group that in civil life it has been the rule, rather than the exception, to consider as early valvular disease. Its frequency in young adults precludes, to my mind, the possibility that many of these cases can be really organic valvular defects, but the murmurs must be interpreted as of little significance and probably of dynamic origin. It must frankly be admitted that we have no adequate explanation as to the causation of these murmurs. However, it is not a matter of great surprise that accidental murmurs occur, but that they do not occur more frequently. The function of the examining physician, in the latter group of cases, is to determine the fitness of the recruit for Army life. This can be done only by a careful consideration of each individual case. The response to a measured amount of work is one of the most practical guides. The effect of the exercise on the patient must be carefully observed. A peculiar look of anxiety and unusual acceleration of respiration are all important signs in determining the exercise response. This group separates itself into two classes on the basis of exercise response: (1) without symptoms, and (2) with symptoms.

Those without symptoms are fit for full military service. This statement is confirmed by the after-histories of a group of these soldiers (Lewis). The class with symptoms is the most difficult one to label; they are probably early cases of organic valvular disease. This class corresponds to the thirty soldiers classified as mitral valvular defect or doubtful group. Electrocardiographic evidence of left ventricular predominance or orthodiagraphic evidence of the so-called mitral configuration is of service in diagnosing these cases.

The ruling of Lewis on apical, systolic murmurs is, to my mind, sound. The systolic murmur per se is disregarded. The soldier is disqualified because of cardiac hypertrophy, not because of a systolic murmur; or is disqualified because of a poor exercise response, not because of a systolic murmur; or his service is limited because of a definite attack of rheumatic fever, and not because of a systolic murmur.

It is to be hoped that the valuable lessons learned from the examination of a large number of young adults will be reflected in the attitude of the medical profession in handling this group of patients in civil life.

SLOW INTRAVENOUS INJECTION OF ANTISERUM TO PREVENT ACUTE ANAPHYLACTIC SHOCK [*]

JULIAN H. LEWIS, PH.D., M.D.
First Lieutenant, M. R. C., U. S. Army
CHICAGO

From the beginning, the great bane of serum therapy has been serum sickness, the occurrence and severity of which can never be predicted. Individuals who do not give a history of previous sensitization often give reactions varying from death to an uncomfortable urticaria in certain diseases in which repeated doses of serum are given; and on the occurrence of successive infections, each of which call for serum treatment, the serum sickness is much more likely to occur and with greater severity.

Since the recognition of the fact that serum disease is a phenomenon of protein sensitization, or anaphylaxis, much research work has been done to find a means to prevent it, and as a result many suggestions have appeared in the literature, most of which have proved worthless or impracticable. On the basis of the fact that most anaphylactic phenomena are due to the contractions of plain muscle fibers, the administration of drugs acting on the sympathetic nervous system has been advised. Netter[1] advised the use of calcium chlorid, but Rosenau and Anderson,[2] Schippers,[3] and Wentzel[4] showed that it had no effect. Barium chlorid, studied by Biedl and Kraus,[5] and atropin, studied by Auer and Lewis,[6] on sensitized dogs, are uncertain in their action, and at any rate are not advisable for human use. Rosenau and Anderson show that a narcotic may mask but does not prevent the occurrence of severe or fatal reactions. In studies made for the analysis of the anaphylactic reaction, it was found by Sleeswijk[7] and Friedberger and Hartoch[8] that there was a diminution of complement in the blood of an animal immediately after anaphylactic shock. In order to prove the significance of this diminution of complement, to show whether it is a secondary phenomenon or whether complement takes an active part in the production of conditions that cause death, Friedberger and Hartoch made use of the fact observed by Nolf,[9] Hektoen and Ruediger[10] and others that hypertonic salt solution (from 1.5 to 2 per cent.) will prevent the combination of complement with its sensitized cells. By slowly injecting into sensitized guinea-pigs 0.3 c.c. of concentrated sodium chlorid solution just before the injection of antigen, they were able to diminish anaphylactic shock markedly, saving animals from injections that invariably killed the controls. There are, however, no reports of the use of this method in the prevention of anaphylactic symptoms in man.

Another method worked out for the most part by Besredka[11] depends on the production of the state of antianaphylaxis by giving minute single or repeated doses of antigen followed in three or four hours by the full injection. Besredka shows that the same results can be accomplished by the rectal injection of from 5 to 10 c.c. of serum, in which case there also occurs a slow, gradual absorption of antigen. While no satisfactory method for producing the state of antianaphylaxis in a sensitized person has yet been devised, owing probably to the important quantitative factors shown by the studies of Weil[12] to exist, either of these two methods of Besredka is the one usually employed in cases in which the administration of serum in the ordinary way is believed to be highly dangerous.

Friedberger and Mita[13] have suggested another method, which depends on the very slow administration rather than division of dose. They showed that many times the fatal dose of serum could be given intravenously to sensitized guinea-pigs if the serum was diluted and given slowly by a specially constructed apparatus, over a long period of time.

When it was shown that the danger and intensity of serum sickness was influenced by the size of the dose of the serum, it was an obviously logical procedure to attempt to concentrate the active elements in antiserums into as small a volume as possible. The methods of concentration developed by Gibson,[14] Banzaf[15] and others have succeeded in making it possible to produce antiserums, principally diphtheria antiserum, which have a very much higher concentration of antibodies. However, the antitoxic property of serum is closely associated with the globulins, which are at the same time closely associated with the production of anaphylaxis; and while the process of concentration does enable one to give large doses of antibodies in a small volume and thereby the occurrence and severity of anaphylaxis is lowered, serum sickness still occurs.

In the practice of serum treatment of pneumonia, which is being established more and more as a success, the occurrence of two facts causes the question of serum sickness to loom still greater as an inconvenience. In the first place, the concentration of antipneumonic serum has not been successfully accomplished as it has been for diphtheria antitoxin. And in the second place, the promulgators of the use of antipneumonic serum advise the use of large volumes of the serum (from 50 to 100 c.c.) injected directly into veins. Both of these factors are no doubt responsible for the many reports of serious anaphylaxis reaction, especially from the army camps, where many cases of pneumonia have been treated with antiserum.

A consideration of the possibilities for the prevention of these unfortunate reactions leads one to believe that the method of Friedberger and Mita, the slow protracted injections of the diluted serum, is the one best adapted to the conditions. This is especially so since we now have an apparatus in the form of the Woodyatt pump,[16] which is ideally suited for the purpose. This apparatus consists of a syringe operated by an electric motor which can be regulated to deliver accurately as small a volume as 0.1 c.c. of fluid a minute directly into the veins. By varying the rate of injection and the dilution, antiserum may be given as slowly as desired. As a matter of fact, this is one of the first uses that suggested itself for the apparatus; and communications from Woodyatt remark the necessity of the study of this procedure.

---

Most manufacturers resort to the addition of tricresol or phenol to serums, in order to preserve their products from bacterial contamination. For this purpose, from 0.3 to 0.5 per cent. of phenols are added. This means that the patient may receive with a single injection as much as 0.5 gm. of phenols directly into the blood stream, and with repeated injections, from 1.2 to 2 gm. in the twenty-four hours. Voegtlin[17] finds that the addition of phenols to serum not exceeding 0.5 per cent. does not impart toxic properties; but on the basis of his pharmacologic observations, he concluded that such preserved serums should be injected at very slow rates.

For the experiments, a series of dogs, rabbits and guinea-pigs were sensitized to horse serum; dogs, by being given 10 c.c. subcutaneously; rabbits, by being given 5 c.c. intravenously, and guinea-pigs, by being given 0.01 c.c. intraperitoneally. After the proper incubation period, these animals could be easily killed by a small dose of horse serum given intravenously.

ANIMAL EXPERIMENTS

Dogs.—The most characteristic phenomenon of anaphylaxis in dogs is a primary fall in blood pressure, a reaction that can be easily registered graphically on a kymograph. Sensitized dogs of about the same weight were anesthetized with ether and one-fourth grain of morphin, and kept under anesthesia through a tracheal cannula. A mercury manometer making tracings on a smoked drum was connected to the carotid artery. Injections were made into the saphenous vein. The injection of 5 c.c. of undiluted horse serum all at once into the vein caused a marked fall in blood pressure, a slowing of the heart, and slow, deep respirations. Death occurred in about fifteen minutes. Injections were made with the Woodyatt machine of 1:10, 1:40, and 1:100 dilutions of horse serum in 0.9 per cent. sodium chlorid solution. The 1:10 dilution at the rate of 0.35 c.c. a minute caused a fall in blood pressure when 0.9 c.c. had been injected. The blood pressure remained low during the five or six hours of injection, but did not kill the animal. The 1:40 and 1:100 dilutions injected at 0.35 c.c. a minute for five or six hours did not cause a fall in blood pressure during the injections. At the end of these injections when 5 c.c. of undiluted serum were given all at once intravenously, there was a fall in blood pressure showing that the animals were not completely desensitized, but enough so that death was prevented.

Rabbits.—Sensitized rabbits of equal weight were injected with 1:10 and 1:100 dilutions. The 1:10 dilution was injected at about the rate of 0.3 c.c. a minute for about six hours. The temperature at the beginning of the experiment was 40 C.; at the end it was 36 C. This rabbit died within one and one-half hours after the injection. The second rabbit was injected with a 1:100 dilution of horse serum. During the first two hours and forty minutes, 44.2 c.c. were injected (about 0.27 c.c. a minute), and in the next three hours, 163.5 c.c. were injected (about 0.94 c.c. a minute). The animal died while the injection was in progress. The third rabbit was injected with the 1:100 dilution. In eight hours and fifteen minutes, 181.35 c.c. were injected (0.3 c.c. a minute). There were no symptoms of anaphylaxis. The temperature showed no alteration. The animal was well and alive the next day, when 2 c.c. of undiluted horse serum were given all at once intravenously. There were no symptoms and no change in the temperature. When 1.5 c.c. of undiluted serum were given intravenously to a similarly sensitized rabbit that had received no preliminary injection with the machine, a very severe reaction was produced, but not death.

Guinea-Pigs.—Given intravenously, 0.01 c.c. of horse serum injected into two similarly sensitized guinea-pigs caused immediate death. With the machine a 1:1,000 dilution of horse serum injected at the rate of 0.3 c.c. a minute into a sensitized animal produced death during the third hour of the injection. Two sensitized guinea-pigs injected intravenously for six hours with a 1:10,000 dilution at the rate of 0.35 c.c. a minute (a total of 0.0126 c.c. of serum) showed no acute anaphylactic symptoms, but both animals died during the following day. In one of these animals the temperature rose from 102.8 F. at the beginning of the injection to 105.6 F. at the end of the fourth hour, and fell to 99.4 F. at the end of the injection.

The experiments with the guinea-pigs were not satisfactory because the prolonged intravenous injections into such small animals are very severe operations. The injections, rather than the action of the serum, undoubtedly caused the death of the last two animals.

CONCLUSIONS

Acute anaphylactic shock can be prevented in sensitized experimental animals by giving otherwise fatal doses of diluted antigen intravenously at very slow rates.

So far as these results can be applied to man, it is to be recommended that when immune serum must be given intravenously, it should be given slowly and in a diluted form, the Woodyatt pump serving as an excellent means of doing so. The exact quantitative relations must be worked out experimentally with patients. At present it can only be said that the injections should be made as slowly and the dilutions as high as is convenient or necessary under a given set of conditions.

BACTERIOLOGIC CONTROL IN THE TREATMENT OF STREPTOCOCCUS EMPYEMA

A. L. GARBAT, M.D. (New York)
Captain, M. C., U. S. Army; Consulting Laboratory Chief to Army Hospitals Nos. 12 (Biltmore), 19 (Azalea) and 18 (Waynesville, N. C.)
WAYNESVILLE, N. C.

In the preliminary report by the Empyema Commission,[1] the importance of the bacteriologic control of the degree of infection or sterility of an empyema cavity was duly emphasized. When the empyema patients were transferred from Camp Lee, Va., to U. S. Army General Hospital No. 12, the study was continued here, and additional observations made which may be of aid in the future therapy of this condition. What is true of streptococcus empyema should also hold true of empyema due to other organisms.

The technic of the culture method was that employed by the commission: Sterile Petri dishes are brought to the ward and in each is placed from 0.1 to 0.2 c.c. of sterile decinormal sodium thiosulphate solution (the thiosulphate is kept in a test tube with a sterile pipet passed through the middle of the cotton plug, and is sterilized by boiling or by steam pressure). When the dressings and Dakin tubes are removed by the surgeon, a long platinum wire with a standard sized loop at its end is passed into the empyema cavity *without touching the walls of the sinus if possible*, and a loopful of secretion is removed. It is thoroughly washed off in the thiosulphate solution in the Petri dish. (Thiosulphate is employed so as to stop the action of any Dakin's solution that might be contained in the loop of secretion.) The plates can be kept until all the cultures of the ward are completed and then taken to the laboratory where the blood agar is poured; or, as was done at the General Hospital No. 12, the blood agar is poured directly in the ward, each plate being completed while the surgeon is finishing the respective dressing. For each plate, 10 c.c. of melted neutral agar in tubes were poured under sterile precautions into a test tube containing 1 c.c. of sterile defibrinated human blood, and the mixture emptied into the Petri dish containing the loopful of secretion. The contents are carefully and thoroughly mixed so as to make an even distribution of the growth and then incubated for twenty-four hours, after which the number of colonies on each plate is estimated.

---

[17] Voegtlin: Bull. 112, Hyg. Lab., U. S. P. H. S.

[1] Cases of Empyema at Camp Lee, Va., J. A. M. A. 71:366, 443, 1918.

In reporting the count to the ward surgeon, the general scheme of the Empyema Commission, with slight modification, was followed:

(*a*) Name.
(*b*) Ward.
(*c*) Plate number.
(*d*) Color (whether normal color of blood or not).
(*e*) Hemolysis. (No hemolysis or percentage of hemolysis of entire plate. For example, plates having many thousands of colonies, counted microscopically, appear almost entirely hemolyzed to the naked eye. Thus, this plate would be designated 90 per cent. hemolysis.)
(*f*) Number of colonies counted. (If the entire plate is counted, the total figure is put down; if the total figure is estimated by counting only a very small fraction of the plate, especially microscopically, the calculation to determine this total amount is placed in this column; thus, 61/20 × 4,570).
(*g*) Total number of colonies (derived from "f").
(*h*) Number of hemolytic streptococci.
(*i*) Number of hemolytic staphylococci.
(*j*) Number of nonhemolytic organisms.

At General Hospital No. 12, we made this division of hemolytic staphylococci because special attention was given to the relationship of hemolytic and nonhemolytic staphylococci to the hemolytic streptococci. No definite conclusions have been reached. While no differences in cultural characteristics of the numerous strains of hemolytic streptococci isolated have been found, the hemolytic zone surrounding the streptococcus colony varied in degree with different strains, giving the impression that the streptococci varied in their hemolytic activity.

It is fully realized that inaccuracies due to this technic are more than probable, but it has been found sufficiently accurate as a comparative guide, if always done the same way on the same patient. The difference of 700 or 1,000 bacteria in a total count is not of paramount importance. Some authorities advise the use of capillary glass pipets instead of the platinum loop so that the identical amount of secretion may be obtained each time. In many instances, however, the sinus leading into the empyema cavity is very tortuous so that the glass pipet is likely to break or secretion from the sinus instead of from the cavity may be obtained. The last contingency is to be strongly warned against, as will be shown below.

The very small percentage of contaminating organisms found is surprising. The cultures usually showed pure growths of hemolytic streptococci. Occasionally, however, when the streptococci had disappeared from the cavity, a new invader appeared, most frequently the staphylococcus. An attempt was made to find a relationship between the growth of the hemolytic streptococcus and the presence of other organisms. In many instances it seemed as if the presence of the hemolytic streptococci in large numbers excluded other organisms; and when the hemolytic streptococci disappeared, the other organisms appeared. In going over the reports of hundreds of cultures, however, this theory was not substantiated. Furthermore, test tube experiments showed no such interference in growth.

Cultures from the cavity were made every few days, in some patients every day. It was interesting to note, as has been described by the commission, that in cases in which the Carrel-Dakin treatment was having the proper effect and the empyema cavity was being sterilized, the number of hemolytic streptococci gradually diminished so that a plate which showed 90 per cent. hemolysis and contained over a hundred thousand bacteria (as is often the case in aspirated pus) would, after thoracotomy and proper Carrel-Dakin treatment for several weeks, come down to complete sterility. Naturally, it is absolutely essential to omit the flushing of the empyema cavity with Dakin's solution for at least six hours previous to taking cultures. On several occasions when the ward surgeons had been changed, a series of sterile plates was obtained because this apparently superfluous advice was overlooked.

If the gradual downward curve of the number of bacteria does not take place or if the curve has been coming down and a sudden rise occurs, some complication in the healing of the empyema cavity exists. The cause is to be found in one of several conditions:

(*a*) A secondary small pouch in direct communication with the large empyema cavity exists, and the communication is such that the Carrel tubes do not enter there; thus, there is growth of bacteria in this small pouch, which constantly feeds into the large empyema cavity from which the cultures are made. In such instances, the bacterial count takes an intermittent curve because on some days the Dakin tubes are so placed that the small cavity is disinfected and a consequent drop in the number of bacteria occurs, while on other days granulations are such that the tubes do not slip into the smaller cavity, with a consequent high number of bacteria in the next culture.

(*b*) Occasionally the necrotic tip of a rib projects into the empyema cavity, and the continuous high count of bacteria from this source persists, and clears up only after the necrotic portion either separates off or is taken care of by the surgeon.

(*c*) In some instances a persistent high count may be caused by a small gauze sponge or piece of rubber tube left in the empyema wound at the time of operation. In such cases, the cultures show types of bacteria other than the hemolytic streptococcus, either alone or in conjunction with the latter.

(*d*) At one time there was a sudden increase in the number of bacteria in almost all patients. Some who were formerly absolutely sterile began to show hemolytic streptococci or other organisms. All possible errors in the surgical technic were excluded. It was found that a fresh supply of bleaching powder was being used which was not very active and which required an entirely different proportion of sodium carbonate and bicarbonate than did the old bleaching powder. The correction of the formula diminished the number of positive cultures. It was the surgeon, Major Moschowitz, who suspected that the error lay in the Dakin's solution, as the wounds showed too much secretion, and the granulations did not look healthy.

When the plates begin to show sterile conditions, cultures are made more frequently than twice a week; and when persistent negative results are obtained, the surgeon allows the empyema cavity to close. As to the number of sterile cultures necessary before this is permitted or the technic employed in closing the wound, each surgeon has his own method. It is agreed, however, by all, that under no circumstances is the wound to be allowed to close when the cavity is not entirely and persistently sterile, thus making the bacteriologic examination a most important factor in the proper therapy of the case.

Several additional facts have been brought out in this study:

1. The blood used for the cultures may be collected with sodium citrate solution (0.3 per cent.) to prevent coagulation, instead of defibrinating the blood. By the use of sodium citrate, very little blood is lost. At U. S. Army General Hospital No. 12, where only human blood was available and large quantities were required, it was important to waste as little as possible. In no way has the sodium citrate been found to interfere with the growth of the hemolytic streptococcus.

2. Cultures should be taken directly from the empyema cavity and not from the Dakin tubes. When these are removed by the surgeon, the ends usually contain a good deal of secretion, and one may be tempted to take cultures from here rather than to introduce the platinum loop into the empyema cavity. Comparative cultures made from the empyema cavity and from the tube always showed a much greater number in the empyema cavity, and in some instances cultures from the tube were sterile while the cultures from the empyema cavity still showed numerous hemolytic streptococci. Thus, the error of allowing the wound to close up too early is possible. This difference in number is readily explained by the fact that the ends of the Carrel tubes usually contain some Dakin's solution from the time it was last introduced into the empyema cavity, and thus disinfection continues there for a much longer period than in the empyema cavity.

3. When the empyema cavity begins to show sterile conditions, separate cultures should also be made from the sinus leading into the empyema cavity. The sinus should repeatedly be proved sterile before the cavity be allowed to heal. Numerous comparative cultures from the empyema cavity and from the sinus showed that hemolytic streptococci persisted in the sinus tract much longer than in the empyema cavity, so that if the empyema cavity is allowed to heal with hemolytic streptococci still in the sinus, reinfection of the empyema cavity is highly probable. The sirus always contains many more bacteria of all kinds than the cavity. The reason for this is as follows: The sinus is usually filled by the Carrel tubes and a short rubber drainage tube; the Dakin fluid runs into the cavity through the Carrel tubes and flows out through the short drainage tube, so that very little disinfectant comes in contact with the sinus. Disinfection of the sinus occurs only once a day, at the time of the dressing, when the whole wound is flushed with the Dakin solution. Thus it is evident that bacteria will persist in the sinus for a much longer period, in much greater numbers and in greater variety than in the empyema cavity. In one patient, repeated cultures from the empyema cavity were sterile, and the sinus showed hemolytic streptococci; but soon the empyema cavity again began to show these organisms, a condition probably due to a reinfection. On the other hand, there are cases in which hemolytic streptococci remain confined to the empyema cavity and never invade the sinus.

CONCLUSIONS

1. Bacteriologic control is of paramount importance in the proper treatment of empyema when the Carrel-Dakin method of disinfection is employed.
2. Cultures should be made from secretion obtained directly from the empyema cavity and not from the Carrel tubes.
3. Cultures, both from the empyema cavity, and the sinus leading into the empyema cavity, should repeatedly be proved sterile before the empyema cavity be allowed to close.
4. A persistently high bacterial count or a sudden increase in the number of bacteria is reasonable basis for assuming some complication in the healing of the empyema cavity.
5. Citrated blood may be used in the blood agar medium.

IRRITABLE BLADDER IN WOMEN*

CHARLES A. L. REED, M.D.
CINCINNATI

Frequent desire to urinate, slight or severe pain with or without straining when urinating, sometimes made worse by emptying the bladder and generally associated with persistent discomfort in the bladder, sufficient frequently to interfere with sleep, are the symptoms of the still other symptom that is here meant by the term "irritable bladder." The cases are generally of long standing and come with a history of prolonged and various treatment, including kidney remedies, washings of the bladder, correction of the uterus, operations on the perineum or rectum or both, and, finally if not all the time, opiates, sometimes resulting in drug habituation. As a rule these patients have lost flesh and have become highly nervous, which results in their frequent classification as "hysterics." They are as a rule sore trials to their medical attendants, the last of whom in desperation has sought relief at the hands of a consultant.

These cases represent real responsibility and call for the most serious and painstaking investigation on the part of those who assume their care. It is this fact that has caused me here briefly to review the real significance of the symptom, which, although a commonplace in our consultation rooms, is one that taxes diagnostic ability to determine not only the various pathologic conditions on which it may depend but also the actual condition on which it does depend in the given case.

GENERAL DIAGNOSIS OF IRRITABLE BLADDER

In looking for the pathologic cause of the symptom, we must remember that the underlying condition is one of abnormal sensibility of the lining membrane of the bladder itself. When we go back of this fact we may do well to recall that it may be caused by conditions either outside of the bladder or inside of it. Those that are outside of the bladder generally produce their effect by pressure and, for the most part, are pregnancy, displacements of the uterus, displacement of the intestine, or tumors of either the uterus or the ovaries. Displacement with sacculation of the bladder itself, often associated with a torn perineum, is to be taken into account. Infection of the fallopian tubes with resulting pressure or adhesions involving the tubes, ovaries and bladder in one mass is a frequent causative condition. Adhesions between the bladder and intestine, induced by the formation of plastic exudate on the peritoneum of the bowel as the result of a static mesenteric circulation or as a consequence of previous operation, have been repeatedly observed in my own work. Inflammation of a chronic character involving the urethral mucosa, especially the nabothian follicles, or ulcerations about the meatus or within the urethra, and urethral neoplasms and urethrocele, are conditions that cause frequent and painful urination and are sometimes taken for irritable bladder in cases in which the bladder itself is not really involved.

---

* Read before the Southern Surgical Association, Baltimore, Dec. 17, 1918.

Among the conditions that arise within the bladder and that have a causative bearing on the symptom under consideration may be enumerated acute infection, generally gonorrheal, but often of the mixed type, the latter depending, I am sorry to say, all too frequently on careless use of the catheter. Tuberculous infection, sometimes primary but generally secondary to that of the kidney, is to be taken into consideration. Neoplasms, both benign and malignant, and calculi may be responsible for the symptom. Four of my patients with prolonged previous histories were readily relieved after discovering that the trouble was caused by diverticula. Two others had sacculated stones. In a few cases, the frequent urination was due to the fact that the bladder had become too small owing to contraction following severe acute cystitis that had been treated by caustic solutions. In a certain proportion of cases, circumscribed and very distinct ulceration, the so-called Fenwick ulcer, near the outlet was found to be the essential pathologic condition.

I have mentioned ulceration last in this brief and incomplete list of intravesical conditions because I wish to devote the most of my paper to another and quite distinct form of ulcer that I am sure deserves more consideration than it has yet received at the hands of the profession. I refer to the condition that has been described by Dr. G. L. Hunner[1] with such originality and distinctness that it has been called the "Hunner ulcer," which I would here designate by the same name if I were not opposed to calling any condition, anatomic or pathologic, by the name of any man. Dr. Hunner himself has called the ulcer "elusive" because of the frequency with which it eludes actual observation in the course of cystoscopic examination. I think it better, however, to use a term that describes some physical and consequently recognizable feature of the condition. I shall, therefore, call it the "punctate" ulcer of the bladder, as being more accurately descriptive of its size and appearance.

IMPORTANCE OF DIFFERENTIAL DIAGNOSIS

Before doing so I wish to speak of the importance of a subject which it is necessary to call earnestly to the attention of the early attendants on these patients, and that is the essential necessity of complete early examination of all bladder cases. It is not sufficient that a patient with bladder symptoms should merely recount her complaints and receive a prescription. Chronic irritable bladder, it should be taught, always depends on some definite local pathologic condition and, as I now believe, in the majority of instances, on the generally overlooked punctate ulcer. While this condition can generally be inferred from the history of the case, its importance, in view of the pain and impairment of health realized, and in view of the treatment required and benefits to be secured, demands that it never be left to a presumptive diagnosis.

CASES OF PUNCTATE ULCER OF THE BLADDER

This condition having been brought forcibly to my attention by Dr. Hunner's contribution to the American Gynecological Society in May, 1918, I recalled five cases of irritable bladder, all of them of long standing and distressing character, in which I had failed to bring more than merely temporary relief by so-called conservative methods. I accordingly sent for these patients to come in again for further investigation and more radical treatment. One, I found, had died from endocarditis following a prolonged and severe multiple arthritis. Four eagerly responded to the overture. One of these four is shortly to submit to operation. The other three patients gladly submitted to operation, and their histories are here briefly submitted as a basis for my further consideration of the punctate ulcer of the bladder, its pathology and diagnosis, and its treatment by excision of the ulcer-bearing area.

REPORT OF CASES

CASE 1.—Mrs. L., aged 34, mother of two children, referred to me by Dr. William H. Tarvin of Covington, Ky., in June, 1912, gave a history of nocturnal enuresis in childhood, for the relief of which at the age of 15 she had submitted to an operation for phimosis. The experience, she said, forced her to control the enuresis, only, however, by getting up from three to five times during the night. She was told that marriage would help; but, although she had since passed through three pregnancies, the painfulness of the bladder had continued with increasing severity. She had exhausted all the kidney medicines on the quack list and had gone to various physicians, regular and irregular, at home and abroad. When she first came to me she complained of pain in the rectum and perineum as being more troublesome than that in the bladder itself. She had to urinate on an average of once every hour, getting up four or five times at night. As a result she had lost flesh, was highly nervous, and wore a haggard look. Examination revealed the rectum free from lesion; the perineum, which had been torn and repaired, was normal, and there was no cystocele. Intense pain in the bladder was elicited by bimanual examination and even on external pressure above the pubes. The urine was clear, acid, free from albumin and sugar, and with only a slight cloud of mucus. Microscopic examination was not made; and if it had been, the real significance of its possible findings would not then have been appreciated. Careful cystoscopic examination revealed a few slightly granular bodies on the rather pale mucosa of the anterior wall. These bled on the slightest touch with a cotton applicator. I looked on the case as one of primary tuberculosis, which I construed as having occurred late in the history of an old cystitis. I resolved on what then seemed to be really radical measures. I treated the condition with thorough gauze curettage over the whole surface and constant drainage, with washings of silver nitrate solution and lavage with sodium bicarbonate in the intervals. The result seemed almost magical, and the patient for the first time in years was free from pain and could sleep all night. This lasted for nearly three months, when all the old symptoms rapidly redeveloped. Two months later she came back and asked to have the treatment repeated. The original appearances were again found and again treated as recounted, this time, however, with less satisfactory results. From that time on she was in a condition of chronic distress, which exceeded only that of her physician who, with his consultant, had to listen to her complaints while having no means to relieve her. June 10, 1918, she returned at my solicitation. I could now find not only some of the old granular bodies or cystic follicles but also a number of punctate ulcers on the anterior wall of the bladder, which area under air pressure was at first pale and then red and then could be observed to crack slightly and bleed. The urine from each of several voidings was found to look clear, but after being centrifuged was found to contain occult blood. These findings with the previous history gave me a positive diagnosis of punctate ulcer which Hunner had conclusively demonstrated to be incurable without excision of the ulcer-bearing area. The operation was accordingly done, June 16, 1918, by the extraperitoneal method essentially after the manner described by Hunner. The convalescence was uninterrupted and the patient went home at the end of three weeks without a symptom of her former trouble. There has not been the slightest return in the six months that have since elapsed.

[1] Hunner, G. L.: A Rare Type of Bladder Ulcer in Women, with Report of Eight Cases, Tr. South. Surg. & Gynec. Assn. **27**: 247, 1914; Boston M. & Surg. J. **172**: 660, 1915; A Rare Type of Bladder Ulcer, J. A. M. A. **70**: 203 (Jan. 26) 1918; Elusive Ulcer of the Bladder, Am. J. Obst. **78**: 374 (Sept.) 1918; Tr. Am. Gynec. Soc., 1918.

Case 2.—Miss G., aged 43, teacher, referred by Dr. F. L. Mitchell of Liberty, Ind., in August, 1915, had suffered with "irritable bladder" for nine years, during which time, like all others of her class, she tried all sorts of treatment. It seemed as if nothing had been omitted from legitimate medicine to the veriest quackery, and I regret to record that the veriest quackery had been quite as successful as the most legitimate medicine. My own efforts to relieve her, except very temporarily, were another addition to the chapter of failures. The relief that I did give for a time was realized by gauze curettage, cauterization with 10 per cent. silver nitrate solution, subsequent alkaline irrigations and constant urethral drainage. Only a few weeks of comfort elapsed before the symptoms returned, and they continued with such increasing severity that the only relief was realized from opiates, the doses of which had grown to 2 gm. of morphin at least three and sometimes four times a day. When I sent for her to come back I found a positive diagnosis of punctate ulcer according to the methods and indications given in this article. Excision of the ulcer-bearing area was done, June 23, 1918. In this instance, however, warned by the hemorrhage in my former case, a complication from which Hunner had lost one of his patients, I did a direct transperitoneal operation by the method which I shall describe. The patient made an uninterrupted recovery and has since been entirely well.

Case 3.—Mrs. T., aged 57, widow, the mother of eight children, was referred to me, Dec. 19, 1916, by Dr. John G. Reed of Elmwood Place, Ohio, who had just been called to the case. The bladder symptoms for which she came had been persistent for fifteen years. She had also been crippled with rheumatism for a number of years and walked with a cane. This circumstance attracted attention to her teeth. She had marked pyorrhea of long standing, with several apical involvements. This circumstance is mentioned only because of the possible etiologic bearings on the bladder condition. The cystoscopic findings were those of what I by that time had come to call chronic granular cystitis. She too, was treated, as in Cases 1 and 2, by gauze curettage, styptics, alkaline irrigation and lavage. This was followed by very marked relief, which lasted for about two months. She then became worse than before and was inclined to blame me for the result. Like the second patient, she could get sleep only by the use of opiates. The reflex pain into the rectum and perineum was especially distressing and was becoming increasingly and intolerably worse. Her general health was breaking rapidly when I requested her return. The examination now revealed all the characteristic conditions of punctate ulcer over a large area of both the anterior wall and the vortex. Excision of the ulcer-bearing area was done, July 1, 1918. The transperitoneal method was employed. The extent of the resection was so much greater than in the preceding cases that I feared the remnant of the bladder could hardly meet its functional requirements. The surgical recovery was without incident. All tenderness of the bladder had subsided by the end of the fourth week. She, however, had yet to get up once or twice during the night in consequence of the diminished capacity of the bladder. This lasted in a diminishing way for about two months more. She now retains 8 ounces comfortably and 10 ounces without much effort.

SYMPTOMS AND DIAGNOSIS OF PUNCTATE ULCER

The diagnosis of punctate ulcer is based on a consideration of the previous history of the case, the present symptoms, the urinalysis findings and the cystoscopic appearances. Other possible causative conditions of irritable bladder, already considered, should first be taken into account and excluded. The previous history of punctate ulcer is that of long duration, persistence in spite of treatment, and gradually increasing severity. The symptoms are frequent desire to urinate, painful urination, pain in the bladder with reflex pain in the perineum and rectum, often with spasm of the sphincter ani and perineal muscle. The urinalysis findings are generally negative except as to the presence of occult blood, which may be intermittent in its presence. I have found Hunner's description of cystoscopic appearance so accurate and so helpful that I give it:

> On cystoscopy, one's attention is not infrequently first arrested by a glazed, dead white appearance of a portion of the bladder mucosa. In such an infiltrated area the vessels may have a broken or "choppy" appearance, only short segments of vessels appearing in the extra pale surface. One may see a dead white scar area with a small congested area in the immediate neighborhood; and while one is examining this area, or after one has touched it, the congestion becomes marked and may even begin to ooze blood. Sometimes an area of edema appears, the mucosa taking on a deep red congested appearance and being raised above the general mucous level. This area of edema may occur immediately about the ulcer area, or it may appear on a portion of the wall at some distance from the ulcer. It may be absent at several consecutive examinations and then appear at a subsequent examination. It is particularly likely to be seen if the patient is in the midst of an unusually bad period of bladder symptoms with strangury.

In certain of these cases I have observed a slight granular appearance suggestive of primary tuberculosis, but which in the light of Hunner's researches we now know to be due to the development of minute cysts with mucous lining.

CAUSES OF PUNCTATE ULCER

The cause of punctate ulcer has not been reduced to a demonstration. In his earlier cases Hunner ventured no conjecture. This was justified in view of the fact that the condition obtained without an antecedent history of bladder infection either gonorrheal or mixed, with no childbearing and no evidence of primary tuberculosis. A little later he became impressed with a possible etiology in focal infection. This was fortified by the frequent coincident occurrence of punctate ulcer with rheumatic and arthritic conditions and by the demonstrated connection of pyorrhea and tonsillar infection with a number of his cases, as in one of the three that I present. This phase of the subject can be developed only by longer observation with a careful collation of facts.

PATHOLOGY OF PUNCTATE ULCER

The pathology of this condition, so far as it has been developed, seems to be that of a chronic interstitial nephritis involving to a greater or lesser degree all the layers of the bladder wall. The involved area seems to become chronically and statically edematous. In certain very limited areas this interstitial process encroaches on the epithelium, and by cutting off the capillary supply causes macular necroses. The areas thus deprived of their epithelium are generally round and from 2 to 3 mm. in diameter. In some instances they are slightly elongated. These minute ulcers seem smaller through the cystoscope than they do after removal. A large number of these ulcers form over a considerable area, generally on the anterior wall and the vortex, and may be from 2 to 6 cm. or more in length and from 1 to 4 cm. or more in breadth. They are sometimes associated with minute cysts of follicular origin. The underlying deep layer of the mucosa is the seat of a true hypertrophy, which by virtue of its permanent character and its influence on the nutrient supply to the epithelium is a determining factor in the incurability of the ulcers, which show no effective tendency to reparative process.

OPERATIVE TREATMENT

The clinical history of these cases, the absence of all tendency to spontaneous recovery, and the failure of all so-called conservative methods of treatment, interpreted in the light of the pathology of the condition and in the light of demonstrated recovery following operation, all point to excision of the ulcer-bearing area as the only rational method of curative treatment. The procedure devised for this purpose, while bold and radical, has the merit of being rational and the added virtue of being successful. The original procedure, as devised by Hunner, the extraperitoneal method, as I understand it, was exemplified in principle with only slight variations in detail by the various steps employed in my first case:

The bladder was filled to distention with a solution containing iodin dissolved in an iodid. The patient was put in the Trendelenburg posture. A Pfannenstiel incision was used to approach the bladder, which was easily reached. The connective tissue, however, did not yield readily in the effort to separate the bladder, especially from the peritoneum covering the anterior wall. The peritoneum was, however, pressed well down from the posterior surface, after which the edematous area, that is, the ulcer-bearing area, could be readily outlined by palpation. Considerable hemorrhage was experienced in this stage of the operation.

The bladder was now collapsed by catheterization and an ellipse of the bladder wall about 6 cm. in length and 3.5 cm. in width was freely exsected. The cut edges of the bladder wall were stretched together by means of fine chromicized catgut, care being taken that there should be no overlapping in the approximation. The peritoneum now came readily over the now resected bladder, and the incision was closed in the usual way, but with a cigaret drain. A mushroom catheter was left in the bladder. The drainage was discontinued in forty-eight hours. The bladder was washed out once daily by gently throwing into it an ounce of a 0.5 per cent. iodized water. The urethral drainage was kept up for fourteen days, the last four of which could probably be set down to excess of caution.

The second method, the transperitoneal procedure, was employed in my second and third cases. This differed from the preceding only in these particulars:

(*a*) The abdomen was opened in the median line from near the pubes to the umbilicus.

(*b*) A vertical incision was made through the cystic peritoneum, beginning on the posterior curvature of the fundus and extending forward and down in front as far as the estimated extent of the ulcer-bearing area.

(*c*) The peritoneum was then peeled back laterally until the fundus could be buttoned out through the slit.

(*d*) The distended bladder was then collapsed by catheterization and the edematous area excised.

(*e*) After this the bladder wall was closed.

(*f*) Over this closure, the peritoneum was stitched together.

In neither of these two cases was there enough oozing to justify drainage; but if subperitoneal drainage should be required, it could be done safely with either a transperitoneal cigaret drain, or by a similar drain arranged extraperitoneally and brought out through the lower angle of the incision. Drainage from the inside of the bladder, if needed, is provided for by the self-retaining catheter.

CONCLUSIONS

1. Punctate ulcer of the bladder, and the pathologic changes associated with it, is a definite clinical entity.
2. The pathologic condition is not only chronic, but also irremediable by so-called conservative methods.
3. The usual limitation of the ulcerative process to the anterior wall and vortex of the bladder makes it surgically accessible.
4. The treatment by excision of the ulcer-bearing area is justified by its demonstrated practicability and by its equally demonstrated results.

5 West Eighth Street.

EMPYEMA FOLLOWING INFLUENZAL PNEUMONIA

OBSERVATIONS ON THE EPIDEMIC AT CAMP GRANT, ILL., SEPTEMBER-OCTOBER, 1918*

MAX BALLIN, M.D. (Detroit)
Major, M. C., U. S. Army; Chief of Surgical Service
CAMP GRANT, ROCKFORD, ILL.

The respiratory diseases became a matter of great and sad interest in our cantonments last winter by the appearance of an epidemic of hemolytic streptococcus infection and again in the fall by the epidemic of influenzal pneumonia. Both affections are quite different from the ordinary lobar pneumonia as we used to see it in our practice, sporadically, and at times in greater numbers approaching small epidemics.

From a surgical point of view, naturally the empyema following these infections is of the most importance. Just as we grouped the pneumonia into three types, I shall here distinguish strictly between: (1) the empyema following hemolytic streptococcus pneumonia; (2) that following lobar pneumonia, and (3) that following influenzal pneumonia as we have it at present.

Last winter, when the streptococcus epidemic struck our camps, surgeons acquainted mostly with the empyema following common lobar pneumonia were of the opinion that an accumulation of pus or infected serum should be evacuated as soon as discovered, and should be drained through wide incision, preferably by costectomy. The results of such early operations in streptococcus empyema were so lamentable that the Surgeon-General sent an empyema commission to Camp Lee to study the question. The report of this commission[1] brought out several points: First, not to operate as long as the pneumonic process was in existence. Second, to aspirate if the quantity of serous exudation in the chest was such as to interfere mechanically with respiration. Third, to operate only after the pneumonic process had subsided, when real pus has formed, by intercostal incision or better by rib resection. These rules were such excellent ones that when the Empyema Commission operated on twenty-three patients at Camp Lee, there was only one death, whereas the previous mortality had been as high as 50 per cent.

---

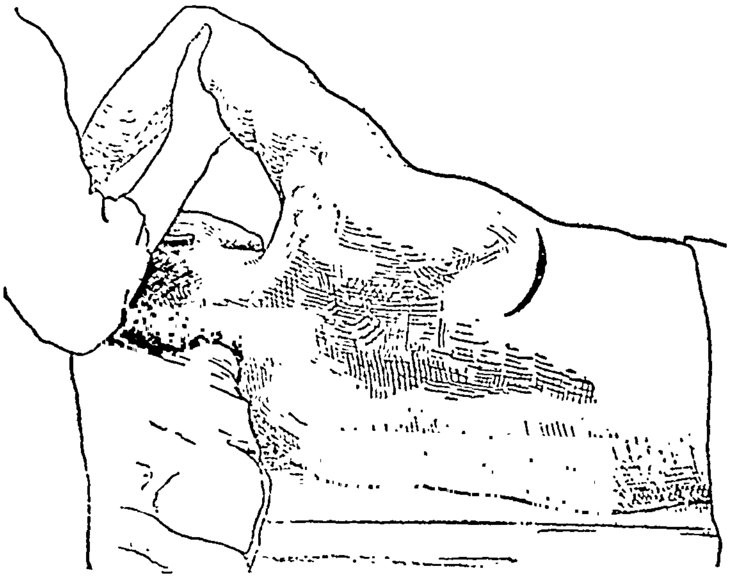

Fig. 1.—Incision made by forming a flap from 3 to 4 inches long, convexity downward, from the postaxillary line backward.

DIFFERENTIATION OF INFLUENZAL AND STREPTOCOCCUS EMPYEMA

The principle laid down for the streptococcus epidemic does not hold good for the influenza epidemic we have just passed through, for the following reasons: The exudation in the chest during the influenza epidemic does not occur early during the pneumonic process, as it did in the streptococcus type. In the latter, we had a true pleuropneumonia in which the exudate was capable of absorption. Often by the fourth or fifth day of pneumonia there was such a large amount (liters) of exudation in the chest that it imperiled respiration by its mere quantity. For these cases, early and repeated aspiration is the rule, whereas costectomy at this time was an error on account of the pneumonic process still existing, and led to a high mortality. In our present, the influenza type, we had hardly any case in which an exudate occurred during the first or second week of pneumonia large enough to cause interference with respiration. We aspirated several cases during the second week, when it was hard to decide whether complete consolidation of the lung or pleuritic effusion interfered with respiration, and never found more than 100 c.c. of cloudy serum. Also, postmortems of the many patients who unfortunately succumbed in the first few days or the second week of influenzal pneumonia did not show large pleuritic exudates; a few times 1,000 c.c. were found, but never enough to embarrass respiration by its pressure. The liters of exudate present in the streptococcus pneumonia during the height of the pneumonic process were not seen this time; therefore the question of early and repeated aspiration in this epidemic is not to be considered. In the influenzal pneumonia epidemic as we have it now, the complications of empyema do not arise before about the fourth week of the illness.

Our epidemic started, Sept. 19, 1918. Our pathologist, Capt. E. F. Hirsch, reported the first necropsy finding of small amounts of seropurulent exudate, October 9; more such cases were found, October 11. On this day the first pus in the living was found by syringe in a case of pneumonia. This patient was aspirated, but only 120 c.c. were obtained. The patient died, October 14. Necropsy revealed only 200 c.c. of the same type of exudate, but a solid consolidation, by bronchopneumonia process, of the whole left lung. The same holds good of many other aspirations at that time. The first empyema of large quantity came to operation, October 19, exactly one month after the onset of the epidemic. Here one may see again the difference between the two epidemics. In the first (streptococcus) epidemic, the pneumonic process itself is accompanied with large pleuritic exudation. In the influenza epidemic, no such early exudate occurs to any extent; there is nothing to aspirate. If an empyema follows the influenza type, it takes four weeks at least to get an exudate that can be called empyema. Before that time we may have small amounts of serofibrinous exudate, which, in my opinion, is capable of being absorbed with the subsiding of the pneumonia, as the large exudate in streptococcus pneumonia.

A second difference of the exudates of streptococcus and influenzal pneumonia is its character. With streptococcus pneumonia we have a thin, gray-reddish fluid with small flakes that change into real pus only very late. The influenzal empyema, as soon as it is of any size, is thick and purulent and contains nearly always more or less, and sometimes, indeed, very large quantities of thick, fibrinous masses. For this reason the former can be easily aspirated by trocars and small tubes. The latter needs drainage through a large opening. Even if mixed infections of pneumococcus and streptococcus are present, the prevailing one will determine the nature of the exudate. In this epidemic the pneumococcus seems to be the predominating organism, so far as our present knowledge of the bacteriology goes.

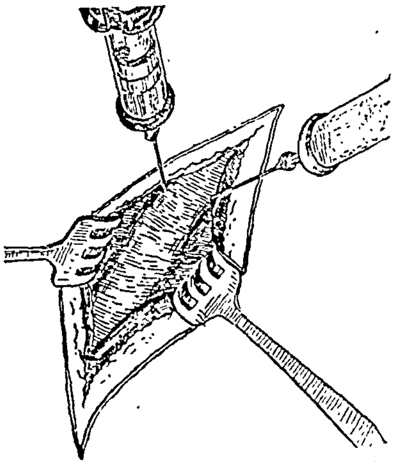

Fig. 2.—Injection of intercostal nerves along the eighth rib with a local anesthetic.

The two main differences, therefore, in the two epidemics are, first, the time of appearance of empyema, and, second, the nature of the empyema. The streptococcus empyema comes early with the pneumonia, the pneumococcus empyema follows the lung process late. The former can be easily aspirated; the latter is too thick for such handling. In the former, open operation should not be performed, but aspiration may be performed, if necessary, on account of pneumonia still existing. In the latter, because of the late appearance of the pneumonic process, operation can be performed with more safety.

---

[1] Review of War Surgery and Medicine, Surgeon-General's Office, 6, No. 1.

DIFFERENTIATION OF INFLUENZAL EMPYEMA FROM THAT FOLLOWING LOBAR PNEUMONIA

After differentiating the present influenzal pneumonia and its empyema from the streptococcus type, we still have to distinguish the present empyema also from the one common after usual lobar pneumonia. From every point of view—the clinical observation, the frightful severity of the pneumonic process, with a death rate of more than 35 per cent., the postmortem findings of a necrotizing, bronchopneumonic process, and also some difference in the behavior of the pneumococcus as to typing, etc.—this influenzal pneumonia is different from the lobar type as we knew it. Whether a special virulent character of a pneumococcus or some other infecting agent is responsible for this difference remains to be seen. The present empyema is thus distinguished from the empyema following the usual lobar pneumonia:

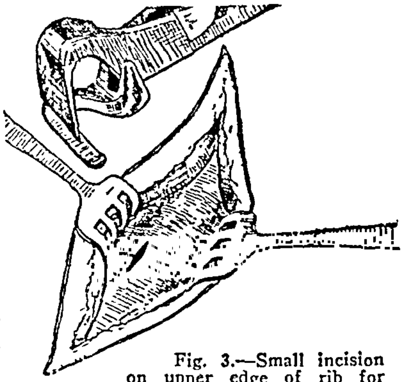

Fig. 3.—Small incision on upper edge of rib for introduction of Doyen's rib shear.

1. It is complicated more frequently by other metastatic abscesses, and for this reason is accompanied by a greater mortality.

2. In roentgen findings, fluid levels are absent. The exudate takes in the whole chest or is encysted.

3. Large lung abscesses are found frequently complicating lobar pneumonia in roentgenoscopies as well as in necropsies. In influenzal pneumonia they are not found.

As to the first of these three points, in this epidemic, the empyema is not of such good prognosis as in those we used to see in the occasional lobar pneumonia. Our death rate for empyema will probably run up to 20 per cent.,[2] and the reason for this is, as I shall show, that the empyema was in most cases only one of the complications following the pneumonia. Often the other lung became infected secondarily by a bronchopneumonic process, or pneumonic meningitis, peritonitis, cholecystitis or deep muscle abscesses existed simultaneously with the empyema. In lobar pneumonia, such complications are rare.

As to the second point, in lobar pneumonia the roentgen ray will show straight fluid levels of the pus filling the thorax; these levels will give a horizontal line in a sitting posture and a vertical line with the patient lying on his healthy side. In influenzal empyema, in seventy-five cases roentgenographed, we have never found a fluid level. The density extended more or less over the whole chest or was of the encysted type. No doubt a difference in infection causes this difference in physical behavior of the pus.

As to the third point, large lung abscesses, as we found them in lobar pneumonia, we have never seen in roentgenograms in 2,700 cases of influenzal pneumonia that we had in this epidemic at Camp Grant or in any necropsies (of which 198 were performed). In opposition to this, in perhaps fifty cases of lobar pneumonia observed at Harper Hospital at Detroit, in 1914 and 1915, we had six lung abscesses complicating recovery. In roentgenograms as well as in necropsies of the influenzal type of pneumonia we find often only small multiple abscesses following the bronchial tree and necrotizing the surrounding tissue, a carbuncle-like process never leading to an abscess of any amount.

We have seen that influenzal empyema follows late, after the bronchopneumonic process has more or less subsided, contains thick pus, and is subject to many complications. For these three reasons, operation should be performed with sufficient drainage as soon as the condition is diagnosed.

DIAGNOSIS OF EMPYEMA

The diagnosis of empyema should be based on: (1) the observation of the patient and his chart; (2) physical signs; (3) exploratory puncture, and (4) the roentgen ray. The chart of the patient is nearly always more or less typical for empyema. After the pneumonic process has disappeared by crisis or lysis, we have an intermediate period of from three to six days free of fever. Then the intermitting pus temperatures of the empyema period begin. This should call our attention to the probability of pleuritic infection. The physical signs—dulness on percussion, abolished respiratory sounds, and lessened vocal fremitus—will be always present if the empyema takes place in the whole side of the chest. But in encysted empyema enough lung tissue may lie over the pus cavity to give respiratory sounds, and air sound on percussion, and these symptoms have kept our medical friends who rely too closely on one symptom from referring patients at the proper time for operation. The exploratory needle will always show pus if the empyema fills the whole chest. But a negative finding, dry tap, should be taken with great caution for several reasons: The needle may not reach the pus. This can be prevented by using needles 3 inches long and thick enough so that they do not become plugged by fibrin masses. In some pneumonias, especially after often repeated aspiration, pyopneumothorax may exist, and the aspirating needle may reach only the air on top of the pus. This can be prevented by letting the patient roll over from his side on his back after the needle has been introduced, so that the air goes upward and the needle reaches the pus. Encysted empyemas are very hard to reach and should be punctured only after studying the roentgenograms closely to get an idea as to the location. Most of them, in my opinion, are of interlobar origin, and can usually be reached higher up in the scapular line. The finding of clear serum in the syringe does not always speak against the presence of pus, because in influenzal exudate, not infrequently sedimentation of the pus takes place, and the upper layer will be clear serum and farther down we find all transitional stages to thick pus. The last word in the diagnosis of empyema will have to be said by the roentgen ray, which fortunately, by means of the modern portable apparatus, may be employed for the examination of the most seriously ill. In classical empyema, the roentgenogram

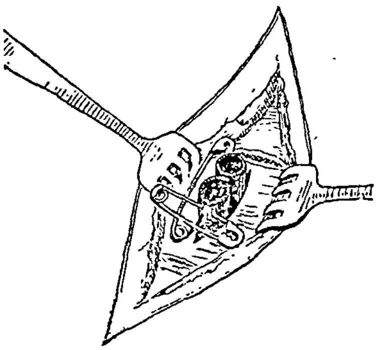

Fig. 4.—Introduction into empyemic cavity of two drainage tubes of soft rubber 3 inches long and one-half inch in diameter, pinned together in the manner shown with two safety pins, so that space is left for the introduction of Dakin tubes.

---

[2] Jan. 22, 1919: The mortality of the influenzal empyema was exactly 19.5 per cent., including all cases of complications.

will show a density over the whole chest corresponding to the dense shadows the liver gives. Encysted empyema will show more or less circumscribed dense areas which, as to their location, should be studied well by fluoroscopy and by the stereoscopic pictures. Only in this way were we able to find pus in every one of the seventy-four cases in which we operated.

After diagnosis has been made certain, there should not be any more delay in operating; and in all these influenzal empyemas, even if encysted, the patients are in such a condition that a classical operation can be done. There is not the counterindication of pneumonia still present, as in streptococcus empyema, and an early evacuation of the pus will to some extent prevent other metastatic infections than already exist. Our friends the internists usually mention cases in which an empyema has been carried for many months by a patient without doing any harm. This is an exception and not the rule; and even this exception has to my knowledge led to deaths by sudden breaking of the abscess into previously noninfected tissue.

TREATMENT

Costectomy is the method of choice for treating the empyema following influenzal pneumonia. Aspirations and intercostal incisions should be only exploratory or temporary measures. In our seventy-eight operations of this series we aspirated only twice to relieve pressure, a day previous to the operation. Once, when a meningitis complicated the empyema, we operated by an intercostal stab.

Only local anesthetics should be employed in operations for empyema. Sudden deaths from suffocation on the table from pus suddenly breaking into the trachea have been so frequent under general anesthetics that it is criminal to give them to these patients. It may happen that the first breaking of an empyema into the bronchus occurs while the patient is on the table. Two of our patients, while being operated on, coughed up several ounces of sputum. Two postmortem specimens showed fairly free communication of the empyema with a large bronchus. Furthermore, the local anesthetic, if administered properly, is fully sufficient to permit one to operate quietly and without causing great pain to the patient. In small children, a whiff of anesthetic will suffice for the operation without abolishing the laryngeal reflex.

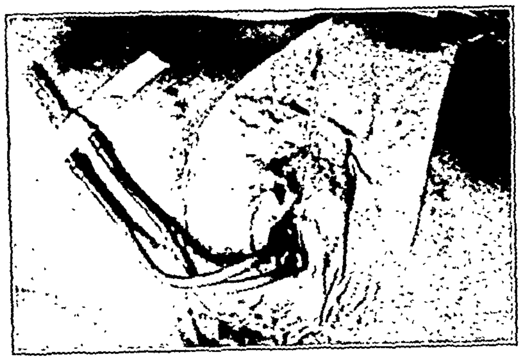

Fig. 5.—Method of introducing Dakin tubes through the large drainage tubes. The latter are fastened securely in the wound with two 2-inch adhesive strips fixed to the safety pins so that no coughing will expel the tubes.

TECHNIC OF OPERATION

The patient lies on the side opposite to the empyema, the arm over the head to elevate the scapula away from the place of incision.

An area in the shape of a parallelogram around the rib to be resected, usually the eighth, is infiltrated with a local anesthetic, a small needle being used for the first injection, followed by a thicker needle 3 inches long to get the whole area from the same puncture hole. The infiltration takes in the skin, subcutaneous tissue and muscles. The middle of the parallelogram lies in the scapular line, and extends backward within 2 inches of the spinal line, forward to the postaxillary line. Infiltration should be deep. The incision made is between 3 and 4 inches long and curves slightly, with the convexity downward. The flap so created is turned upward, including skin, fascia and superficial muscles until the eighth rib appears clearly. Two or three muscle vessels require ligatures. The intercostal nerve, along the eighth rib, is then injected below and above the rib. This injection is made carefully so that the needle does not enter the nerve before a few drops of solution are injected; otherwise the patient will complain of severe neuralgic pain in the intercostal nerve. This injection is important; it renders the rib section practically painless.

A small cut is made on the upper edge of the rib, and a Doyen rib shear is introduced around the rib and pushed backward and forward until 2 inches of the rib are exposed. The rib is cut first anteriorly and then posteriorly. The pleura is incised in the space from which the rib piece was removed. Pus begins to appear immediately and is emptied by turning the patient slowly backward. Any obstructing fibrin masses are removed with forceps. A double drainage tube pinned together with safety pins is introduced into the pleura surrounded by two pieces of gauze in the wound of the chest wall, and this is fastened securely in the wound by two 2-inch wide adhesive straps fixated to the safety pins attached to the tubes. This is important so that no coughing will expel the tubes. If neutral solution of chlorinated soda (Dakin's solution) is used, two small Dakin tubes are introduced through the large drainage tubes. A large absorbent pad covers the whole. These drainage tubes with the surrounding gauze are not changed for a week. The outer dressing is changed when necessary. The Dakin tubes, if used, are changed daily.

If in cutting the rib, injury to the intercostal artery should happen, it is ligated by a transfixing ligature, the artery being caught central to the lesion with some of the surrounding muscle fibers. There are no sutures put into the wound, as drainage will continue better without sutures closing the ends of the wound and creating a bottle-shaped abscess cavity. The curved flap will fall into the chest wall defect after the drainage is removed, or is drawn in by an adhesive plaster strap.

RESULTS

By this technic we have operated on seventy-nine patients. Of this number we have lost eleven, or about 14 per cent., and we shall probably lose a very few more by pyemic process; but this figure loses its significance, as to the value of the method, if I state that two of the patients that died had an extensive suppurative pneumococcus meningitis: two had empyema on the other side; one had gangrenous cholecystitis; two had abscesses in the mediastinum; two had endocarditis, and two had gangrenous bronchopneumonic processes in the other lung. No uncomplicated cases have been fatal, in spite of the fact that a good many of these patients were in a very low condition at the time of operation. Three patients with empyema on both sides were operated on in this series with an interval of two weeks in two cases and of three weeks in one case between the operations. Six of the patients living and operated on had metastatic abscesses; many had bedsores when transferred, showing the serious condition they were in at the time of operation. In 62 per cent. of the empyemas there was pure pneumococcus infection; in others, mixed pneumococcus and hemolytic streptococcus infection. The deaths were about evenly divided between the two groups. The first thirty empyema patients were treated with neutral solution of chlorinated soda. Of this group, eight died. Since then, the forty-nine remaining patients have been given dry treatment, with only three deaths.

While the first thirty patients may have been more seriously ill than the later ones, which is the case in many epidemics, the difference in the death rate speaks against the Dakin treatment. To anticipate the usual remark this statement provokes: The Dakin treatment was given in the proper way, adhering to all the details as to its administration.

In the after-care of these patients, proper attention is paid to caloric feeding, which is important to replace the immense loss of tissue substance caused by the profuse suppuration and also to fresh air and early muscle exercise. Special care is taken to elevate the arm on the operated side at every dressing, to prevent rigidity of the muscles. In the first cases of operation, healing is now taking place, one month after operation.

CONCLUSIONS

We have to differentiate in the treatment of empyema between three types:

1. The empyema following hemolytic streptococcus infection. This occurs early as an exudate in the first week of the pneumonic process, is thin, very copious, and capable of being absorbed, and should be handled, if necessary to relieve pressure, with aspiration, operating by costectomy, only after the pneumonia has subsided.
2. The empyema following lobar pneumonia. This sets in four weeks after pneumonia, is of good prognosis, and can safely be handled with costectomy.
3. The empyema following influenzal pneumonia. This also develops four weeks from the onset of the process. On account of serious and frequent metastatic suppuration, its prognosis is more severe than that of Form 2. It is best handled by thorough drainage, by costectomy under local anesthesia.

English Crime Figures.—Annual number of convictions for crime in Great Britain had fallen greatly prior to the war; since then the drop has been still more marked. Convictions, according to the British Prison Commission's report, fell steadily from 184,901 in 1908-1909 to 139,424 in 1913-1914, and during the war period the number was 104,000 in 1914-1915, 58,839 in 1915-1916, 43,678 in 1916-1917 and 32,773 in 1917-1918. The population of the prisons of England and Wales per hundred thousand in 1900 was 483.4, but has now sunk to 88.7. Convictions for drunkenness fell from 51,851 in 1913-1914 to 3,692 in 1917-1918. Those for men in the former year were more than double the convictions of women, while in the latter year convictions of women were considerably in excess of those of men. The lessening of convictions for crime is accounted for by various conditions arising out of the war, and for drunkenness on account of the restrictions on the sale of alcohol, chiefly, perhaps, notwithstanding the rise in wages and greater prosperity of the classes formerly most given to drink. A social system which could facilitate the means of employment while at the same time maintaining sobriety at its present level, would incidentally find in such measures the solution of the penal problem.—*Medical Officer.*

FRACTURE OF CERVICAL VERTEBRAE, WITH RESTORATION OF BONY SUBSTANCE

L. F. LUCKIE, M.D. (Los Angeles)
Major, M. C., U. S. Army
GERSTNER FIELD, LAKE CHARLES, LA.

As I was not present at the time this injury was received, I give excerpts from the written statement of the patient, who was a lieutenant in the Aviation Service:

History.—Statement by patient: "Feb. 11, 1918, about 4:45 p. m., Lieutenant M. and I, who were on a cross country flight, fell at Jennings, La. Lieutenant M. was killed instantly, and I was rendered unconscious. Local doctors treated me and shipped me back to the post hospital, Gerstner Field, La., where I was treated for a broken right clavicle, broken nasal bone and a bruised knee. Treatment continued for about six weeks, at the end of which time thirty days' sick leave was granted me. I had continuous boring headaches and pains running down my arms. I could not move my head, which was drawn over to the right side and forward. Before leaving the hospital, however, on my sick leave, roentgen-ray pictures were taken in which it developed that I had fractured fourth, fifth and sixth cervical vertebrae, with partial dislocation between the fourth and fifth. . . .

Fig. 1.—Front view of patient before treatment, showing typical deformity of dislocation of cervical vertebrae.

"On my arrival at home, Richmond, Va., I went to see a surgeon, who examined me carefully, and then sent me to another physician, who in turn sent me to another physician to have roentgen-ray pictures taken. After examination and study of these the doctor decided that the only treatment possible for my injuries was an electric baking process (thermotherapy). I then consulted my surgeon again and he sent me to Johns Hopkins Hospital, Baltimore. There I was examined by three physicians, and they decided that an operation was not necessary and that nothing could be done, but advised me to consult another doctor of Johns Hopkins. He said the bones were ground off and nothing could be done. However, he advised me to have a leather collar made, which I was to wear six weeks or more, at the end of which time I was to be treated by an electric baking process (thermotherapy). I returned to my home in Richmond, and again consulted my surgeon, who said he would write the particulars of my case to the post surgeon, Gerstner Field, La. All this time I suffered with boring headaches and pains in my arms. After my leave expired I returned to Gerstner Field, La., and went under the care of Major L. F. Luckie, M. R. C., who had, in the meantime, become post surgeon."

Examination: June 1, 1918, the patient came under my care. His head was drawn forward and to the right, the muscles were stiff and hard on the right side, and his face showed that he was suffering pain. He complained of boring headaches and pains in his arms, and stiffness of the muscles of the right side of the neck, and was very much discouraged in regard to his condition. I examined the roentgenograms that had been taken of this patient before he left the hospital on leave of absence and immediately ordered him to be placed in bed, his whole appearance showing that he was an ill man. He grew morbid, and when told that we would try to do something for him, seemed indifferent to any suggestion of treatment.

Treatment.—Turkish towels were wrung out in hot water and applied to the patient's neck for twenty or thirty minutes, and then his neck was massaged with camphorated oil. This was done to soften the muscles in preparation for the appliance that I was constructing for him to wear. The dentist was requested to take plaster-of-Paris impressions of the back of his head and neck and of his chin to the angles of the jaws. I then took these impressions and ran models. I obtained two pieces of sole leather of medium thickness, soaked them thoroughly and placed them on the cast, burnishing them down so as to fit the cast of the chin and the back of the head. I then placed the impressions over these casts, tying them together and letting them dry in the sun. I then measured the height from the shoulder upward as far as I wished the point of the uprights on my appliance to extend, making the pattern of these from malleable metal, bent as shown in the illustrations. Pads were made for the shoulders, metal strips were made to fit these pads, and the uprights were soldered to the metal strips. These were then laced on the pads. Two pieces of metal were then placed before and behind, horizontally, reaching from one metal strip to the other, set with winged nuts so the appliance would not move outward or inward. A belt was attached by leather strips before and behind and placed around the lower border of the ribs; straps were placed on the chin piece and head piece, these straps extending upward to small bolts with eyes, the bolts running through an opening in the vertical supports. The straps were threaded through the loops of the bolts and could be lengthened or shortened by turning the winged nuts or using buckles on straps or turnbuckles on each of the uprights, permitting raising or lowering of the patient's head. June 10, this appliance was placed on the patient, and gradually, each day, the winged nuts were tightened so as to bring the head into the proper position. The hot applications and massage were continued daily.

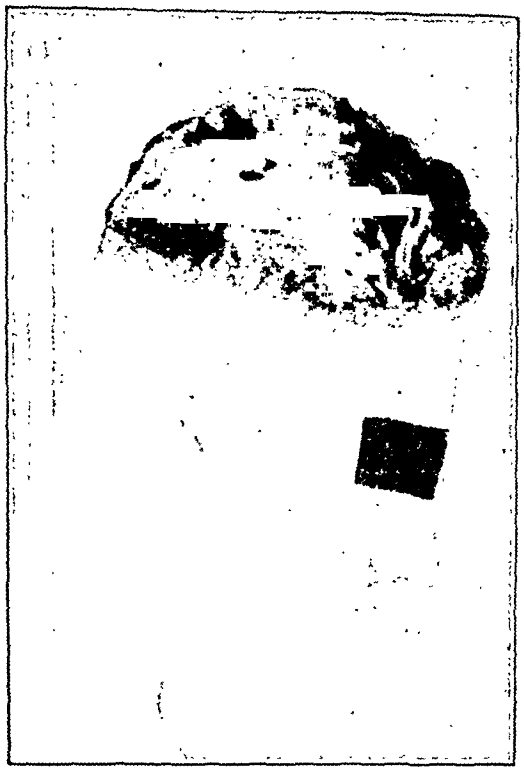

Fig. 2.—Side view of patient before treatment.

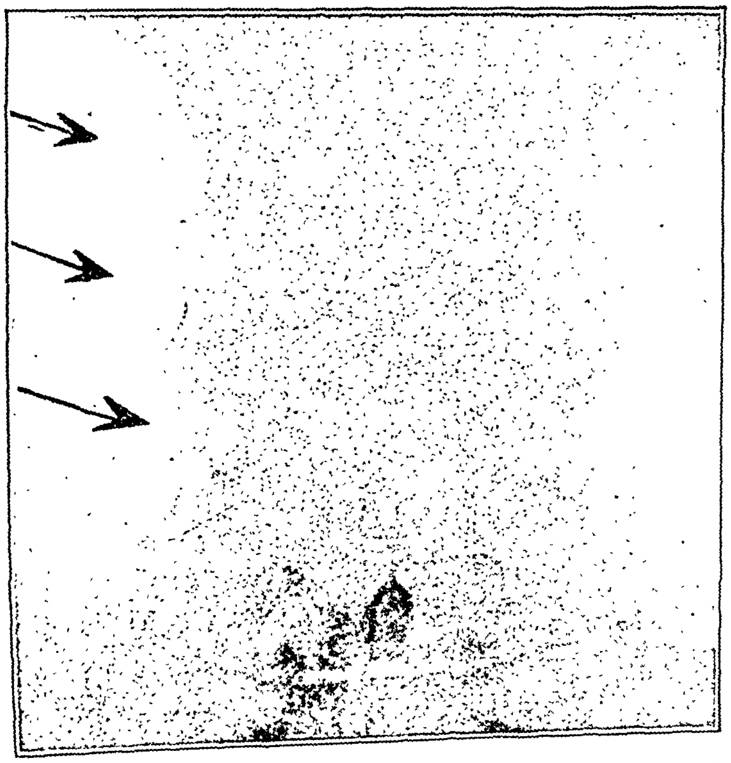

Fig. 3.—Anteroposterior view, showing fracture of vertebrae as well as dislocation of the fourth vertebra.

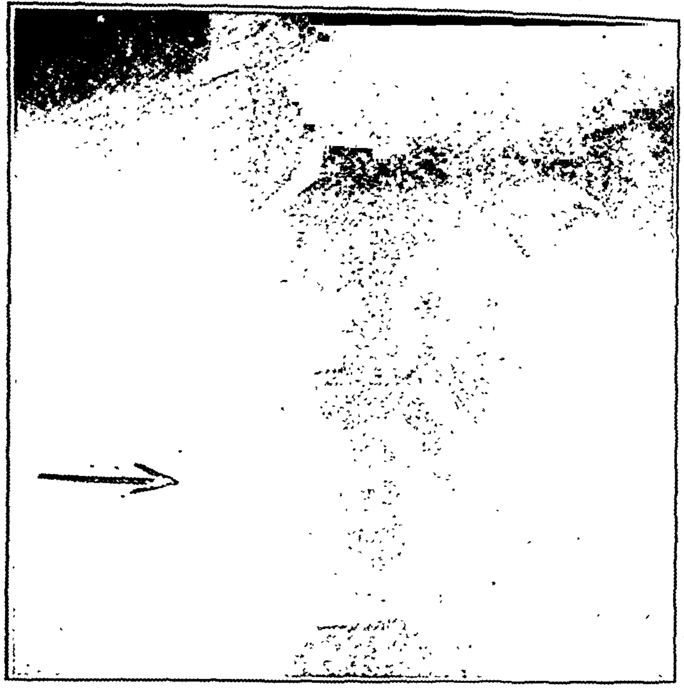

Fig. 4.—Side view, showing dislocation; by Dr. Gray, Richmond, Va.

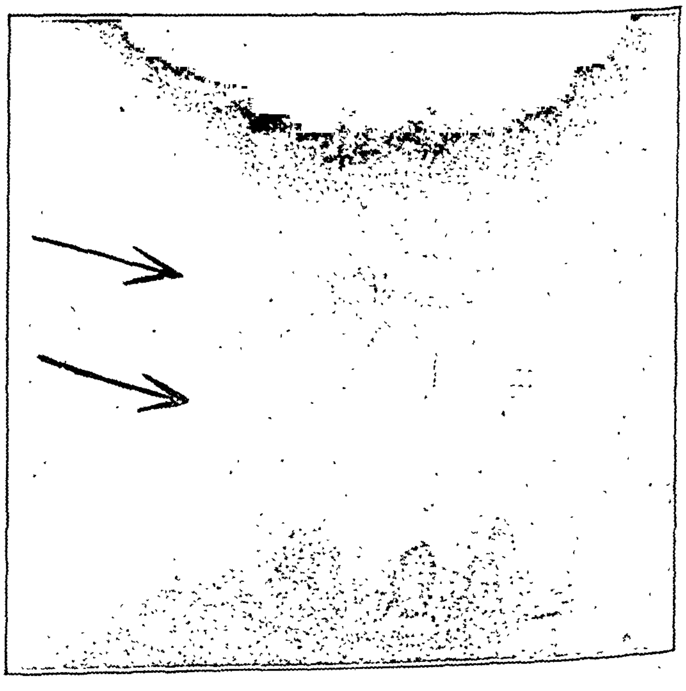

Fig. 5.—Condition after return of patient from leave.

This appliance literally hung the patient from his own shoulders, and was the only treatment, outside of massage, that was used in this case. The value of the appliance was that immobilization was obtained and the vertebrae were separated and held separated, so that the new bone cells were protected and growth and recalcification of bone permitted.

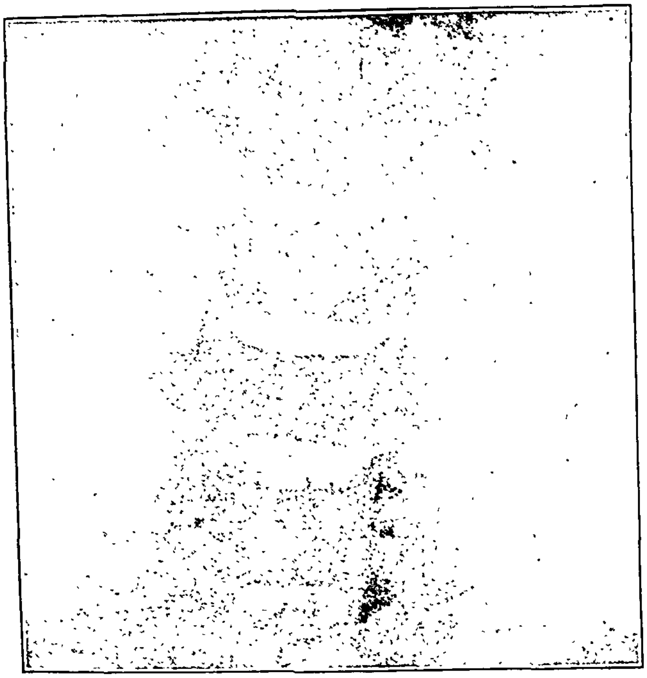

Fig. 6.—Condition, August 23, the day the appliance was removed.

Another advantage of this appliance is that it permitted the patient to be out of bed, thereby keeping up his physical strength and his spirits. Another very important advantage was that the patient never took the appliance off for massage or for sleep, thereby keeping the neck on a stretch all the time that he was under treatment.

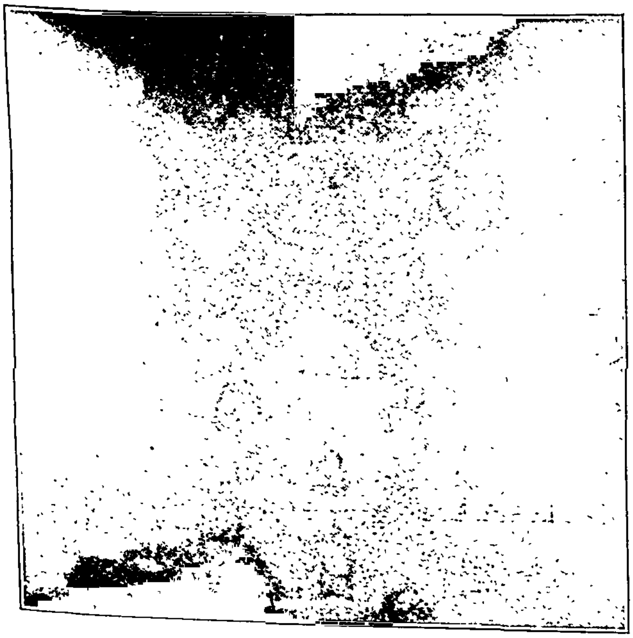

Fig. 7.—Condition eighteen days after appliance was removed.

It has been the common custom in spinal cases to place on patients a plaster-of-Paris jacket, after first stretching them by the different methods in use. After the stretch has been relieved, the patient's vertebrae rest on each other again, and the result is that few patients, if any, ever recover completely, because the bones are still grinding on the new cells that Nature is trying to form, and absorption of bony substance takes place.

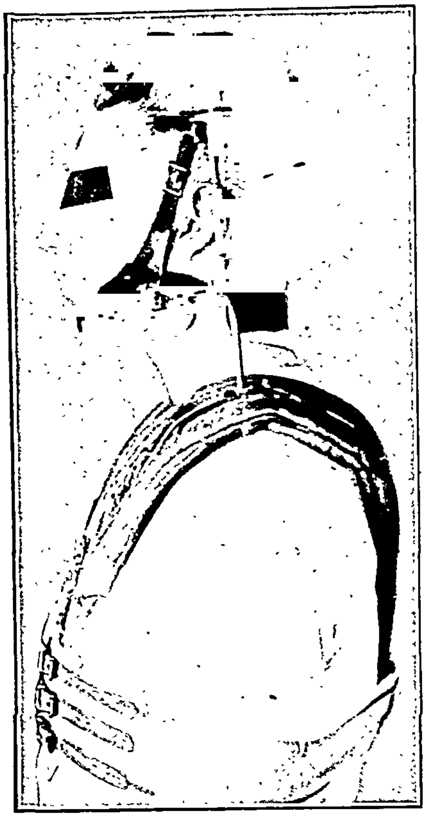

Fig. 8.—Apparatus in place: Patient hung from his own shoulders continuously.

In the patient's statement of his case it will be noted that he told that the bones had been ground off. This is shown in the roentgenograms.

Interesting observations that may be noted are:

1. The appearance of the patient's face before the brace was put on (Fig. 1).
2. Typical position of the head in dislocation of the cervical vertebrae (Figs. 1 and 2).
3. The absorption and ground off appearance of the bones in Figure 3, taken at this post before the patient's leave, and in Figure 4, taken in Virginia.
4. The outline of the vertebrae, after removal of the appliance, August 23 (Fig. 6), and also *the condition* shown in Figures 12 and 13 as compared with Figures 1 and 2.

The pain in the head and arms began to disappear twenty days after the treatment had been begun, and has entirely disappeared.

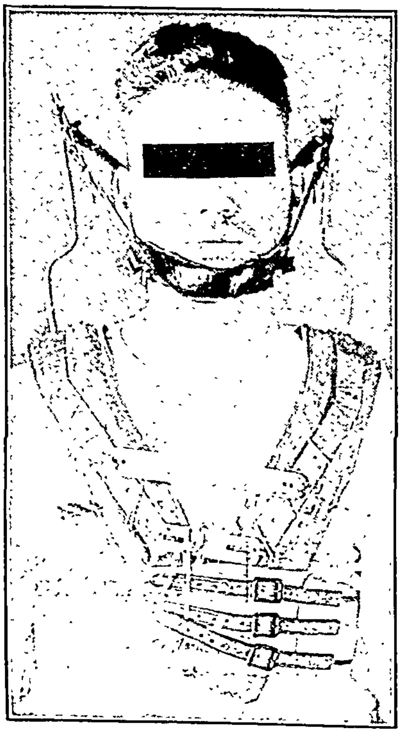

Fig. 9.—Apparatus in place; front view.

This is the only case on record of a pilot's breaking his neck in an areoplane accident and being sent back to flying duty again. With the exception of a stiffness of the muscles from long-continued wearing of the appliance, and ankylosis between the fourth and fifth vertebrae, which occurred before the case came under my care, this patient is in good shape and fine spirits.

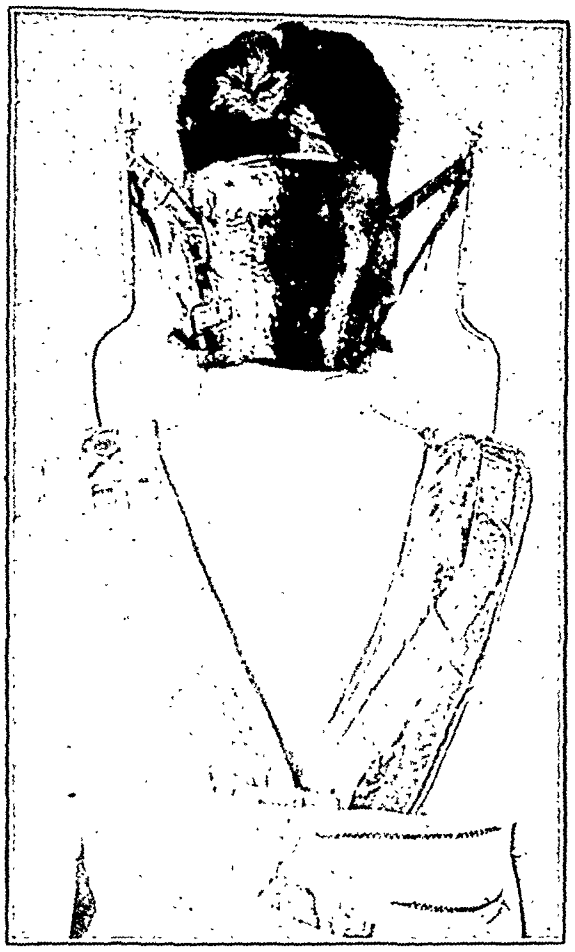

Fig. 10.—Apparatus in place; rear view.

He was happy to be able to work again for his country, with new inspiration to do his work better, if possible, than before.

It may be interesting to note that he passed the low oxygen test, which carries with it the test of the eyes, etc., by the Medical Research Laboratory, Sept. 4, 1918, and was graded in Class A, in which there are no restrictions as to altitude. The patient also took the revolving chair test for equilibrium and passed in Class A.

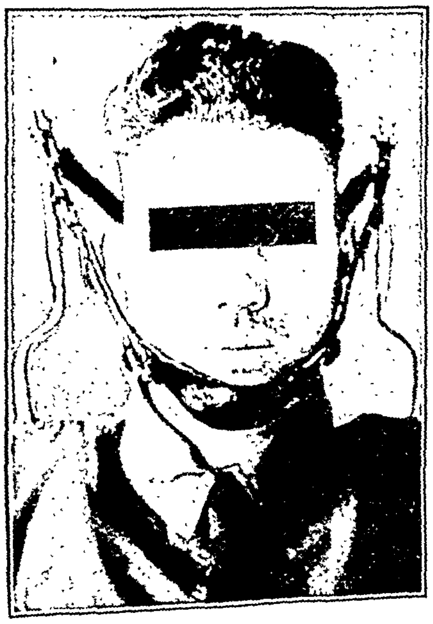

Fig. 11.—Patient dressed; shirt especially designed for wearing with appliance.

The appliance was made at this post, Sergeant Taylor of the machine shop doing the steel work, and the post shoemaker stitching the straps on the chin and neck piece. The idea for the appliance was suggested by the case of my father, the late Dr. J. B. Luckie, who was the first surgeon in the world to set a broken neck successfully.[1] His appliance was a modified Sayre jury mast with a plaster-of-Paris jacket. Although the patient lived for twenty-six years after having had his neck set, he could never do without the appliance.

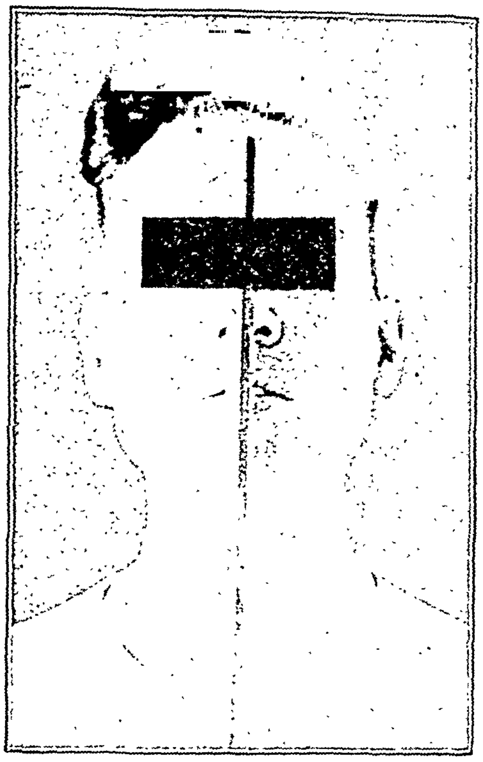

Fig. 12.—Result of treatment; front view. Compare with Figure 1.

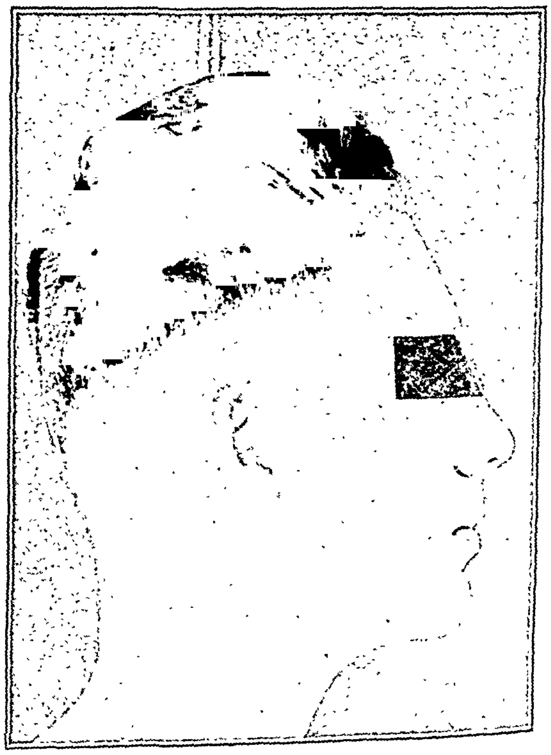

Fig. 13.—Result of treatment; side view. Compare with Figure 2.

The roentgenograms were taken by Lieutenant Cornica, M. C., of this post, and two by Dr. Gray of Richmond, Va. The photographs were taken by Lieutenant Erickson, post photographer.

Clinical Notes, Suggestions, and New Instruments

A NEW METHOD FOR THE STUDY OF BACTERIA [*]

W. D. FROST, PH.D., DR.P.H., MADISON, WIS.
Professor of Agricultural Bacteriology, University of Wisconsin.

The rapid identification of bacteria is a matter of the greatest importance. Certain organisms have characteristic morphology or staining reactions, but in most cases it is necessary to make a culture of the organism before it can be identified, a process that requires hours or even days.

Modifications of a method that I have already described[1] furnish a means of studying the morphology of the cells and the colonial structure of young cultures of bacteria, many of which show very interesting and, I believe, distinctive characters in a surprisingly short time, that is, in from three to five hours.

The medium in its simplest form is a 50-50 mixture of nutrient agar and sterile milk.

The apparatus is of such a simple nature that it will be found in all bacteriologic laboratories. It includes pipets, microscopic glass slides, platinum needles, an incubator, common stains, etc. The pieces of apparatus that could be called special are a "moist chamber cabinet," a warm plate for drying the films, and forceps for handling microscopic slides; but makeshifts for these are easily found in the common equipment of all laboratories.

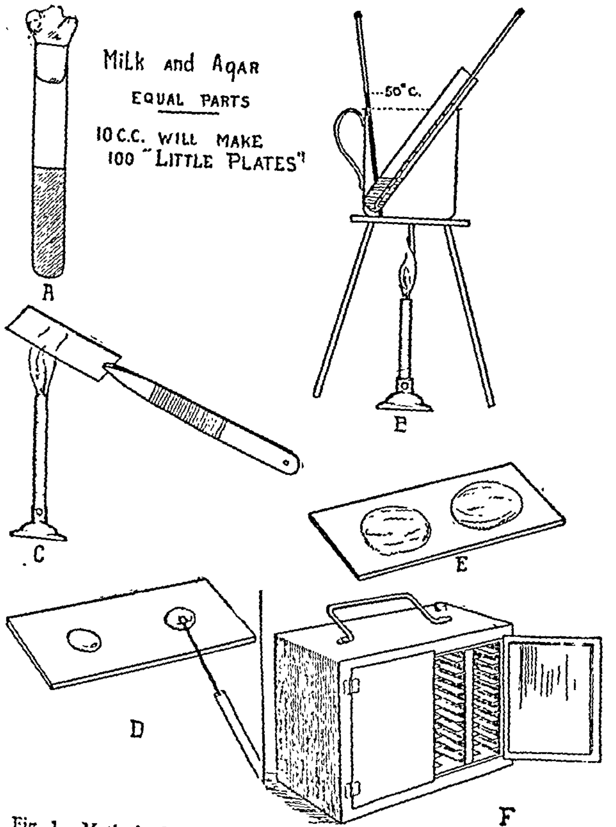

Fig. 1.—Method of making "little plates": *A*, milk and nutrient agar, sterilized separately and mixed in equal quantities; *B*, medium, melted and ready for use; *C*, flaming the slide; *D*, inoculating the medium and spreading the drops; *E*, slide ready for incubation in the moist chamber, *F*.

METHOD OF MAKING CULTURES

A clean glass slide is sterilized in the direct flame and placed on the table. When it has cooled down there is placed on it, from a pipet, two separate, medium-sized drops of the culture medium, which has been previously melted and cooled to about 50 C. Into one of the drops of the culture medium, the material containing the bacteria to be cultivated is introduced by means of a platinum loop and thoroughly mixed, while at the same time the drop is spread over the slide in a thin film. When the first drop is spread, the loop is carried over to the second drop, which is thus inoculated with a small fraction of the same material. This drop is spread in the same way as the first. As soon as this is done, the slide is put in a moist chamber and placed in the incubator. In this way two little plates are made on the same slide from each sample to be examined, containing quite different amounts of the inoculum.

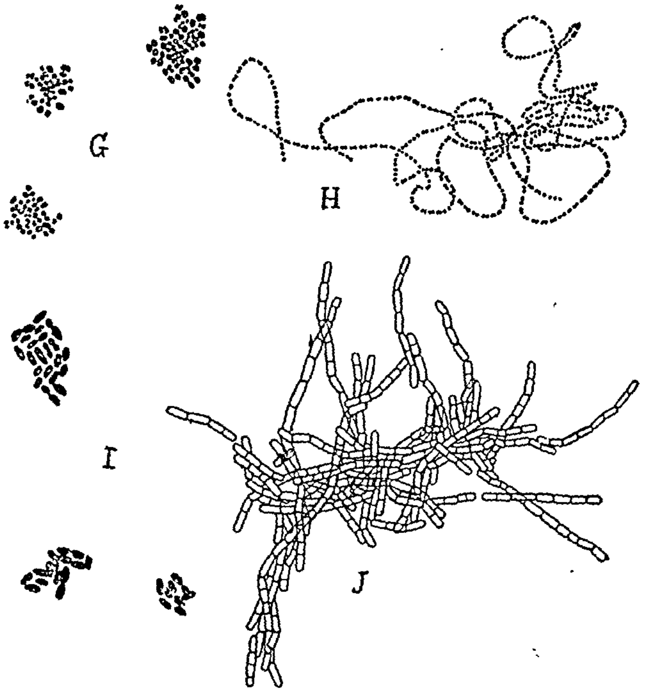

Fig. 2.—Colonies, four hours old, of organisms grown on the "little plates"; *G*, Micrococcus pyogenes var. aureus; *H*, Streptococcus pyogenes (?), from a throat culture; *I*, Bacillus coli; *J*, Bacillus subtilis. The drawings were made by Miss Margaret Brown under the camera lucida, and give the relative size as well as the shape and arrangement of the individuals in the colony.

It is necessary to work rapidly in making these "little plates" in order to prevent the agar from hardening before it is spread. It is also necessary to use aseptic technic at every step, except that I have not found it necessary to take any special precautions against air infection during the preparation of the plates, or to keep the edges and underside of the glass slides sterile. The method is illustrated in Figure 1.

INCUBATION

Immediately after being made, the little plates are put in a moist chamber where they are kept until the colonies grow to sufficient size to be examined. A few slides, as a makeshift, may be put in Petri dishes, the bottoms of which are covered with wet filter paper, on glass rods which keep them from getting wet. It is much more convenient, however, to have a "moist chamber cabinet" and when a large number of slides is used, it is quite necessary. Such a cabinet, especially designed for this work, is represented in Figure 1 *F*.

Whatever the form of the moist chamber, it is put in an incubator and kept at the temperature best suited to the needs of the organisms under study. The colonies usually attain sufficient size in the course of three or four hours to give the characteristic arrangement of the cells. If the colonies are allowed to grow much larger, the individuals become so massed that only those at the periphery are distinctly discernible, so that there is usually no advantage in large colonies.

When the "little plates" are removed from the incubator they are taken from the moist chamber and dried. The drying is an important step and is apparently best done rapidly by placing the slides on a warm plate kept at a temperature just below 100 C.

---

[*] A part of the expense connected with this and further work of the same kind, now in progress, was met by an unknown business friend of Madison, who made his contribution through Prof. C. S. Slichter, chairman of a university committee on research.

[1] Frost, W. D.: A Rapid Method of Counting Living Bacteria in Milk and Other Richly Seeded Materials, J. A. M. A. **66**: 889-890 (March 18) 1916.

STAINING

When the slides are dry, they are ready for staining. They are put first in a 10 per cent. solution of acetic acid in 95 per cent. alcohol for one minute or more. They are then drained and put in Loeffler's methylene blue diluted 1:4 with distilled water. The slides are allowed to stain from two to three minutes and are then washed free from the stain in a jar of tap water. They are dried and are then ready for microscopic examination.

With practice it is soon possible to make these preparations in such a way that the colonies are deeply stained with the individual cells well differentiated and the background clear. The best results are usually obtained after the stain has been used for some time. For this reason the stain is used, in jars, over and over, rather than poured over the preparations fresh each time. So far, a diluted Loeffler's stain has been used exclusively; but it seems quite possible that other formulas can be developed and that perhaps other stains than methylene blue can be used to advantage. For example, it may be possible to use a red stain, such as fuchsin or safranin, which would be very desirable, especially in photomicrographic work. It is also quite possible, indeed, very probable, that stains can be used to bring out the metachromatic granules in the diphtheria and other germs. The double spore and the Gram stains have been successfully used.

AN IMPROVED SPINAL PUNCTURE NEEDLE AND PRESSURE APPARATUS

Abraham Levinson, B.S., M.D., Chicago

It is now generally recognized that spinal puncture is one of the most useful diagnostic procedures, and that the pressure of the cerebrospinal fluid is a useful guide in the diagnosis of many diseases of the nervous system. Many needles have been used for doing a spinal puncture since Quincke first described the procedure. In using most of the needles, however, one is unable to tell whether or not he has reached the subdural canal until he has withdrawn the stylet entirely. If the canal has been reached, the fluid comes out with a greater or lesser force on removal of the stylet, and by the time the manometer is introduced into the needle, as for instance in the Quincke apparatus (Fig. 1), too much fluid has been lost to give a correct pressure reading; for it has been found that the pressure is greatly lessened, even if only a few drops of cerebrospinal fluid have been removed.

In order to prevent the loss of fluid in taking the cerebrospinal fluid pressure, and in order to make it easier to determine whether or not one has reached the subdural canal, I have devised the apparatus and method herein described.

The apparatus (Fig. 2) consists of a specially devised needle and a glass manometer.

The needle is the ordinary medium sized spinal puncture needle with a short piece of glass mounting and a stopcock. The glass tubing (*A*) enables one to see whether the spinal canal has been reached with the first puncture. One need only withdraw the stylet beyond the glass tubing, and if the spinal canal has been reached, the fluid withdrawn will be seen immediately through the glass. If no fluid makes its appearance, the stylet can be inserted again and another attempt made. The fear of breaking the glass on boiling the needle for the purpose of sterilization is no objection. I have boiled the needles repeatedly, without ever breaking the glass.

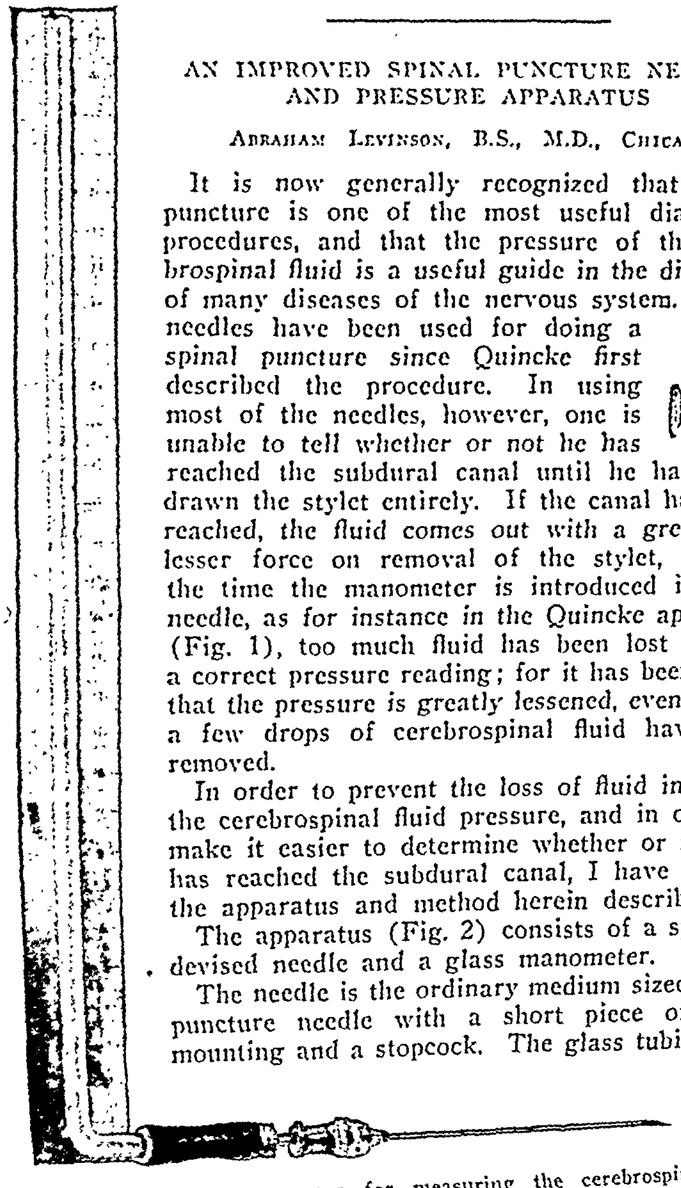

Fig. 1.—Quincke apparatus for measuring the cerebrospinal fluid pressure.

The needle has a three-way stopcock (*B*), the distal end of which is about three-fourths inch long. This length is required in order to allow space from the stopcock to the end of the needle so as not to lose any of the fluid, as is the case when the valve of the stopcock is near the end of the needle. The stylet of the needle is long enough to reach from the distal to the proximal end of the needle.

The manometer (*D*) consists of a long glass tube of 1 mm. bore which is inserted into the projecting end of the needle (*C*). The glass tubing is 700 mm. long, as this was the highest pressure attained in any case studied. For convenience, it is divided into two portions, with a metal cap at the top of the first portion so that the other one can be screwed on. This makes the manometer convenient to carry in any small instrument case. Thick glass tubing is used for it so that it does not break easily in handling. A metal tape is attached to the glass to measure the pressure.

The needle (with the piece of glass tubing at the end, the stopcock and its prolongation) with the stylet inside is introduced into the spinal canal. After a snap has been felt, so that one is reasonably certain the subdural canal is reached, the stylet should be removed to a point beyond the glass attachment. If fluid is seen in the glass tubing, the stopcock (*B*) is turned at right angles so that the handle points upward. This shuts off the needle and prevents the fluid from coming out. The long glass tube (*D*) is then attached and the stopcock turned so that the handle points opposite the manometer. The fluid will then rush into the tube. When the fluid has mounted to the highest point, the pressure is read off in millimeters of water. If no fluid is seen coming out when the stylet is removed beyond the glass tubing, the stylet should be reintroduced until the operator feels he is in the canal. It should then be removed beyond the glass, and the measurement taken. The handle is now turned parallel to the needle and the fluid collected in test tubes. The whole needle, including the glass attachment, stopcock and prolongation, is not any heavier than an ordinary medium-sized spinal puncture needle.

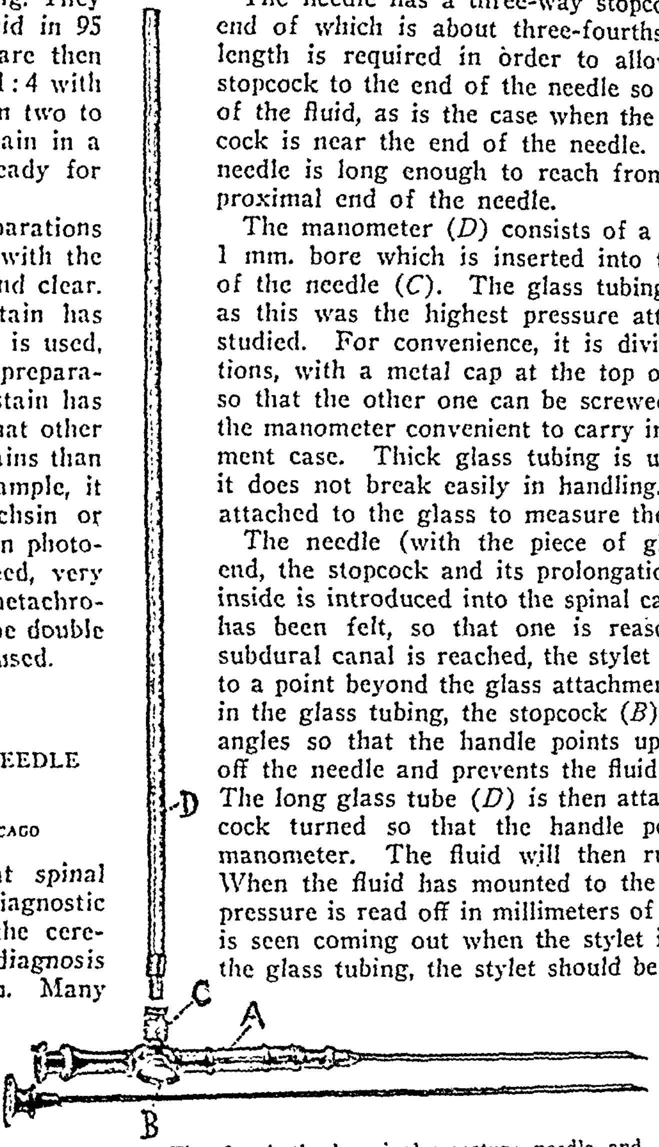

Fig. 2.—Author's spinal puncture needle and manometer: *A*, glass tubing in the needle; *B*, stopcock; *C*, upper projection of the needle into which the manometer is introduced; *D*, glass manometer.

The apparatus is made by Becton, Dickinson & Co., Rutherford, N. J.

A SIMPLE ALL GLASS ATOMIZER

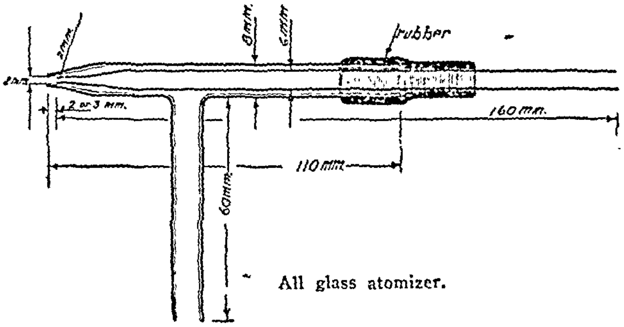
H. S. Newcomer, M.D. (Philadelphia) and W. S. McEllroy, M.D. (Pittsburgh), Philadelphia

Lieutenant and Lieutenant, Junior Grade, respectively, U. S. N. R. F.

The accompanying illustration gives the construction and approximate dimensions of an all glass atomizer which may be readily constructed from ordinary glass tubing and at a cost of only a few cents. It consists of an outer piece which is an 8 mm. glass T tube. One end of the T is drawn out to a nozzle. Another nozzle, slightly smaller, is drawn from a piece of straight 6 mm. glass tubing. The latter nozzle is inserted within the first in such a way that the tip of the inner nozzle is 2 mm. behind the tip of the outer nozzle and concentric with it. The opening of the outer must be a little larger than that of the inner one so that the air stream from the inner nozzle will have an unobstructed path. The inner nozzle should be nearly in contact with the walls of the outer nozzle. Both the nozzles must be in longitudinal section slightly concave outward, and neither should be at all constricted at the tip by flaming.

The two tubes, inner and outer, are fastened together in place with a piece of rubber tubing. Under some circumstances it may be preferable to seal them together in the flame. An ordinary atomizer bulb with its tube slipped over the end of the inner tube furnishes the necessary air current. The absolute dimensions of the atomizer may be varied considerably. One exactly half the size described (about the size of the illustration) works very well.

The free leg of the T is dipped into the liquid to be atomized, or the T may be inverted and a small quantity of the liquid poured into it. The atomizer works in any position, is readily taken apart for cleaning, and can be boiled in a shallow dish. It is especially adapted for use with heavy oils, such as a solution of dichloramin-T in chlorcosane.



All glass atomizer.

Naval Medical School.

New and Nonofficial Remedies

The following additional articles have been accepted as conforming to the rules of the Council on Pharmacy and Chemistry of the American Medical Association for admission to New and Nonofficial Remedies. A copy of the rules on which the Council bases its action will be sent on application.
W. A. Puckner, Secretary.

SULPHOICHTHYOLATE PREPARATIONS

Preparations containing as their essential constituents salts or compounds of a mixture of acids containing sulphur and designated by the group name "sulphoichthyolic acid" are manufactured from certain bituminous shales. Sulphoichthyolic acid is characterized by a high sulphur content, the sulphur existing largely in the form of sulphonates, sulphones and sulphides. The ammonium compound of this so-called sulphoichthyolic acid—first introduced as ichthyol—has been used most extensively. Compounds with sodium and other metals, with albumin, with formaldehyde, etc., have also been introduced.

Actions and Uses.—The current estimate of the effects of sulphoichthyolic acid preparations is based almost entirely on the use of ichthyol. As it is not known to what constituent or constituents of ichthyol such effects as it may have are due, the actions of ichthyol cannot be transferred to similar preparations which differ from ichthyol in their composition. The use of sulphoichthyolate preparations is still largely empirical. They are considered weakly antiseptic and mildly irritant. They penetrate the skin to some extent and are said to cause some vasoconstriction on mucous membranes. Taken internally they produce some gastro-intestinal irritation, with diarrhea, etc. Their influence on metabolism has not been determined.

They are used locally under the supposition that they will secure the absorption of swellings and effusions in contusions, burns, etc., and especially in gynecologic practice, and in various skin diseases. They have been tried internally in a great variety of conditions, but their therapeutic value in many of their suggested applications has not been fully established.

ITTIOLO.—Ammonii Sulphoichthyolicum.—An aqueous solution, the important medicinal constituents of which are ammonium compounds containing sulphur in the form of sulphonates, sulphones and sulphides. These characteristic forms of sulphur result from the sulphonation of the tarlike distillate obtained from the bituminous shales of Giffoni Vallepiana, Italy, and containing the fossil remains of fish.

Actions and Uses.—See general article on sulphoichthyolate preparations above. The composition of ittiolo closely resembling that of the original ichthyol, it is claimed that its actions and uses are also essentially those of ichthyol.

Dosage.—Since this article is claimed to be closely similar to ichthyol its dosage is probably like that of the older preparation (see N. N. R., 1918, p. 160).

Manufactured by Societa' Industrie Chimiche, Giffoni Vallepiana, Italy (Guiseppe W. Guidi, New York, distributor).

Ittiolo is a browhish-black syrupy liquid having a characteristic empyreumatic odor and burning taste.

It is almost completely soluble in water; incompletely soluble in alcohol and ether, but almost completely soluble in a mixture of equal volumes of alcohol and ether; also soluble in a mixture of equal volumes of alcohol, water, and ether. It is miscible with glycerin.

The aqueous solution of ittiolo (1:10) is faintly acid to blue litmus. The aqueous solution (1:10) yields a greenish-black resin-like precipitate upon the addition of hydrochloric acid. This precipitate is nearly insoluble in ether; it is partially soluble in alcohol; soluble in water, but if dissolved in the latter solvent it is again precipitated by the addition of hydrochloric acid. With barium chloride test solution the aqueous solution of ittiolo (1:10) gives a brownish-black precipitate which is insoluble in diluted hydrochloric acid.

Boil an aqueous solution of ittiolo (1:10) with potassium hydroxide test solution. Ammonia is evolved.

Incinerate 1 Gm. of ittiolo. 0.14 per cent. of residue remains.

Dissolve 10 Gm. of ittiolo in 90 Cc. of water, place the solution in a glass stoppered cylinder and allow to remain undisturbed for twenty-four hours. Only a slight deposit is formed.

Ittiolo loses 51.33 per cent. of its weight when dried at 100 C.

Weigh from 5 to 6 Gm. of ittiolo into a flask, add 25 Cc. of potassium hydroxide test solution and 100 Cc. of water. Distill the mixture until no more ammonia passes over, collect the distillate in 15 Cc. of normal sulphuric acid volumetric solution to which one drop of methyl orange test solution has been added, and titrate the excess of acid with tenth-normal potassium hydroxide volumetric solution; the amount of normal sulphuric acid volumetric solution consumed corresponds to 5.16 per cent. of total ammonia (NH_3).

Weigh from 5 to 6 Gm. of ittiolo into a beaker, add 50 Cc. of water, and 10 Cc. of a ten per cent. solution of albumin, followed by 5 portions of 5 Cc. each of diluted hydrochloric acid shaking after each addition. Make up the mixture to a volume of 500 Cc. and filter through a dry filter. Heat 200 Cc. of the filtrate to boiling, add 10 Cc. of barium chloride test solution and allow the mixture to stand for twenty-four hours. Collect the precipitate of barium sulphate, heat and weigh. The weight of barium sulphate obtained corresponds to 6.2 per cent. of ammonium sulphate.

Weigh from 0.5 to 1 Gm. of ittiolo into a Kjeldahl flask, add 30 Cc. of water and 5 Gm. of potassium chlorate followed by 30 Cc. of nitric acid and evaporate the mixture to about 5 Cc.; add 25 Cc. of hydrochloric acid and evaporate to 5 Cc.; again add 25 Cc. of hydrochloric acid and evaporate to 5 Cc. Then add 100 Cc. of water, heat to boiling and add 10 Cc. of barium chloride test solution, allow the mixture to stand for twenty-four hours, collect the precipitate of barium sulphate, heat and weigh. The weight of barium sulphate corresponds to 8.87 per cent. of total sulphur. Calculate the ammonia contained in the ammonium sulphate, as previously determined in ittiolo, and subtract the result from "total ammonia" as previously determined. Multiply the remainder by the factor 1.88. The result represents the sulphur present as "sulphonic sulphur." Calculate the sulphur contained in the ammonium sulphate as previously determined in ittiolo, and subtract the result from "total sulphur" as previously determined. The remainder represents the sulphur present in the organic sulphonic acids contained in the substance. Subtract the "sulphonic sulphur" as previously calculated, from the sulphur in the organic sulphonic acids, as previously calculated. The remainder corresponds to 0.66 per cent. ("sulphide") sulphur.

Ittiolo is incompatible with acids and saline solutions, fixed alkalies, their carbonates and iodides, alkaloidal salts and mercuric chloride.

QUININE ETHYL CARBONATE-MERCK.—Quininæ Æthylcarbonas.—Euquinine.—$C_2H_5O.CO.O.C_{20}H_{23}N_2O$.—The quinine ester of ethyl carbonic acid. First introduced as euquinine.

Actions and Uses.—Those of a nearly tasteless and insoluble quinine compound.

Dosage.—The same as quinine.

Merck & Co., New York, distributors. No. U. S. patent or trademark.

Quinine Ethyl Carbonate-Merck Tablets, 2 grains.—Each tablet contains quinine ethyl carbonate-Merck 2 grains.

It occurs as a light, fleecy conglomeration of delicate white needles, which are practically tasteless.

It is sparingly soluble in water, but readily soluble in alcohol, ether and chloroform.

It is slightly alkaline in reaction, forming well crystallizable, bitter salts with acids.

Quinine ethyl carbonate melts at 89 to 91 C.

Dissolve about 0.2 Gm. of quinine ethyl carbonate in 5 Cc. of dilute sulphuric acid and dilute to 50 Cc. The solution exhibits a strong blue fluorescence, and responds to the general tests for alkaloids. Add 2 or 3 drops of bromine test solution to a 1 Cc. portion of the solution followed by 1 Cc. of ammonia water; the liquid acquires an emerald green color due to the formation of thalleoquin.

Dissolve 0.2 Gm. of quinine ethyl carbonate in 5 Cc. of nitric acid and dilute to 25 Cc. To a 5 Cc. portion add 1 Cc. silver nitrate test solution. No precipitate is formed (*chloride*). To another 5 Cc. portion add 1 Cc. barium chloride test solution. No precipitate is formed (*sulphate*).

Add 5 Cc. of iodine test solution to about 0.2 Gm. of quinine ethyl carbonate, decolorize with sodium hydroxide test solution and warm. The odor of iodoform is manifested (*ethyl group*).

Incinerate about 0.5 Gm., accurately weighed. Not more than 0.1 per cent. of residue remains.

THE "HEALTH RATE" OF A NATION

Among the many lessons that the war has helped to teach, few have been more significant than the demonstration of the unexpectedly large number of persons who, from a military standpoint, are physically unfit. The more progressive nations have for some years devoted much consideration to the problems of national vitality, and sanitary science as well as practical hygiene has gained a more prominent place in the estimation and the budgets of enlightened communities. Perhaps, however, Arthur Keith was right in saying that the mistake which we have been making is that of keeping our eye too exclusively on the birth rate and death rate and neglecting what he cleverly designates the "health rate."[1] Without doubt the young men of the English-speaking nations, at least, have been shown by the elaborate physical examinations, undertaken as a part of the military arrangements of the respective countries, to be far below that ideal standard of fitness which might be expected for a virile race.

The almost appalling statistics of the examinations made in this country by the medical boards have been referred to from time to time. Keith[2] has presented the conditions that prevail in England in statistical terms which indicate the outcome of grading young men from one of the large British industrial towns. In place of having 900 men, out of 1,000, more or less fit for physical employment in civil life, only 460 could thus be counted. It may be objected that the present population of such towns and cities represents for the most part only the residue after the fit and active men have gone out to military service; but Keith ventures to assert confidently[1] that even when this possibility is taken into account there can still be no illusions as to the large numbers who are physically far below the standards for their ages.

Well defended assertions of this sort, which can doubtless be duplicated from American experiences, at once raise the question as to the most probable causes and the appropriate remedies for an admittedly undesirable condition. Broadly speaking, it resolves itself into the much debated question as to the comparative influence of environment and heredity in the development of the individual. One "expert" will tell us that the growing numbers of the physically unfit are attributable to the results of slum life, or to the necessity of wage earning by mothers who are consequently unable to look after their children. The obvious inference is that the living conditions of a large group of our population must in some way be improved. Another group of investigators will remind us, on the other hand, that there is a danger of promoting racial harm if assistance is freely granted to families without regard to their personal or moral worth, that is, their hereditary stamina, for expenditure tending to improve hygienic conditions may incidentally promote fertility. What would be more irrational than to breed unfitness in the attempt to eliminate it?

The dilemma is of more than academic interest. National health is demanding more prominent consideration than has been accorded to it either here or abroad in the past. In the United States the desirability of having the Public Health Service recognized more prominently as an independent department of the government has been widely discussed. In England the project of a ministry of health seems likely to succeed. The prime minister, Mr. Lloyd George, has awakened the imagination of the English by the terse remark that it is impossible to maintain an A 1 empire with a C 3 population. He took pains to emphasize, by way of explanation, that greater attention ought to be paid to the home, "the most important workshop in the land," because it turns out human beings, the most delicately constructed of all human machines.

Leonard Darwin, son of the eminent biologist Charles Darwin, has pointed a warning against possible misinterpretations of the widely quoted A 1-C 3 catch phrase.[3] He reminds us that if the steel of which a tool is made is not of good quality, a good article cannot be turned out even in the best workshop; that is, the child must be both endowed at birth with good racial qualities and born in a good home if the result, the finished man, is to be of the best quality. From this standpoint the progressive reformer who aims at increased national efficiency must be conversant not only with modern sanitation and the proposed devices for social uplift, but also with the investigations of the experimental biologist. Both eugenics and "euthenics," as the scheme for environmental betterment has been termed, must find a place in the new attempts to improve the "health rate" of the nation.

Even the most enthusiastic propagandists for eugenic matings among mankind realize how visionary their schemes are amid a society of present-day make-up. No one will object if postwar efforts to secure increased national vitality are directed toward promoting biologically sane marriages. It seems well worth while, however, to point out, as Leonard Darwin has also done, that we must not count the C 3 man whose disabilities are due to wounds of war or accidents of peace as unfit for parenthood. The belief in the inheritance of acquired defects has long been abandoned. A wounded combatant, one of the thousands now returning to their homes, is just as likely to "be the father of heroes" as any uninjured civilian. A man's physical injuries in no way compromise the racial qualities of his descendants.

Lastly, let us not make the blunder of measuring fitness solely from the standpoint of physical prowess. Moral and intellectual virtues have often been found in relatively frail bodies. We need men and women who have a clear intellect and a tender conscience—the higher type of individual whose body is the ready servant of a superior will.

THE FAILURE OF GERMAN COMPULSORY HEALTH INSURANCE

Prior to the entering of the United States into the world war, social insurance was under general discussion in medical, public health, social reform and philanthropic circles. Eight states appointed commissions to investigate the subject and submit reports and recommendations. With the return of peace it is highly probable that this discussion will be resumed. While the American Medical Association has taken no definite stand on the fundamental questions involved, it has, by the adoption of the resolutions[1] presented to the House of Delegates in New York in 1917, indicated a minimum basis on which the medical profession will cooperate in case the plan is adopted by any state. To the majority of physicians the question is an open one on which they are keenly desirous of securing all the information possible. Much has been written in favor of social insurance from an economic and public health standpoint; many claims have been made regarding results in other countries; but little has been written in the form of definite criticism of the proposed plan and its results elsewhere. For this reason, the paper presented before the twelfth annual meeting of the Association of Life Insurance Presidents by Mr. Frederick L. Hoffman will doubtless arouse considerable discussion.

The primary purpose of the establishment of compulsory social insurance in Germany, according to Mr. Hoffman, was to hinder the rise, curtail the power, and ultimately destroy the socialistic movement in Germany. "By means of a cleverly devised terminology and downright methods of deliberate deception, the German working people were deluded into the belief" that compulsory health insurance was primarily intended for their benefit. In this way the German government hoped to bring about the complete subjection of German wage earners to the will of the bureaucratic and political machine. "All compulsory social insurance," says Mr. Hoffman, "rests on profound misconceptions of life and labor in a democracy, for it involves the establishment of permanent class distinctions." After thirty years' trial in Germany, compulsory health insurance, he asserts, has not improved the health of the working portion of the community or the standard of public health, while financially it is at present in a condition of chaos. It has increased malingering among employees to such an extent that only 26.6 per cent. of the alleged illness in Leipzig was found to be real. As to the claim of improvement in the health of employees, in 1884-1885, in Dresden when the fund was established, the percentage of employees claiming sick benefit was 30.4, while in 1913, after twenty-nine years of operation, the percentage was 32.2; in other words, the amount of illness among the insured after thirty years of insurance was greater than it was in the beginning. There were 27.7 per cent. of deaths from tuberculosis among male wage earners, as compared with 21 per cent. for the same class in the United States registration area. Regarding financial conditions, the report of the sick fund for Königsberg for 1917 shows that expenditures have increased 75 per cent. as compared with 1915, and that the assessment on wages has been raised from 4.5 per cent. to 6 per cent. to meet this increased expense. Dishonesty and deception on the part of patients, druggists and physicians, with a general undermining of the morale of the community, are also charged. Some of Mr. Hoffman's conclusions bear on the social results of compulsory insurance. It has not checked the spread of socialism in Germany, he asserts, but has increased the demand of workmen for additional benefits; it has not improved the economic condition of the German wage earner, since the benefits that it provides were never adequate to meet more than the requirements of the minimum standard of living. It has not reduced disease nor improved public health conditions. In the field of sanitary reform the United States, in the last thirty years, he declares, has advanced far more rapidly without social insurance than Germany has with it. The death rate in Germany has not diminished proportionately, as it has in this country. The condition of the medical profession in Germany has not been improved, but, on the contrary, the ethical standards of the profession have been perceptibly lowered. The sickness rate among German wage earners has not been reduced; increased demands on the funds both now and in the future will require either increased contributions from wage earners, withdrawals from the financial reserves, or both. The system has resulted in a lowering of social and individual morality and has fostered deception, dissatisfaction and dissimulation. The German experience, in

---

[1] J. A. M. A. 68:1755 (June 9) 1917.

Mr. Hoffman's opinion, proves the inadequacy of social insurance as an effective means of securing the required degree of continuous social progress demanded by modern standards of labor and life.

Mr. Hoffman's conclusions will doubtless be challenged by the advocates of social insurance. The charges he makes against German-administered social insurance are serious. If sustained by the evidence, they are entitled to serious consideration. In determining his attitude on the question, every physician must avail himself of all the information he can secure on both sides of the question and weigh the evidence for and against. Mr. Hoffman's paper is a specific attack on the proposed social insurance plan, and as such should be considered by the student of the subject.

THE PROBLEM OF WOOD ALCOHOL POISONING

The dangers of intoxication with methyl alcohol (wood alcohol) are beginning to be recognized more widely than was the case a few years ago when all "alcohol" was popularly assumed to be essentially similar to grain spirits in its behavior in the organism. The occasional instances of harm that attended the use of wood alcohol in the industries were scarcely sufficient to give a due warning of the danger from this substance. However, when wood alcohol began to be drunk with fatal results by the "toper" who could not obtain his accustomed alcoholic beverages, and when large numbers of serious poisonings from the use of whisky adulterated with wood alcohol came to public notice, the real menace of methylated spirits to health began to be appreciated. Both acute and chronic poisoning with methyl alcohol give rise to serious damage to the optic nerves as the most conspicuous and distressing symptom.

The foremost reason for the unlike physiologic behavior of the two commonest alcohols lies in the unlike readiness with which they are oxidized in the body. Ethyl alcohol may be excreted to a small degree through the eliminatory organs; but for the most part it is burned up much as are the ordinary foodstuffs. Hence the contention that alcohol may be a food. Methyl alcohol, on the other hand, is oxidized with difficulty. More than half of a nontoxic dose may find its way out of the body again through the respiratory channels. Furthermore, the progress of the elimination of the unoxidized portions is comparatively slow, so that the output from a single dose may even continue during an entire week. As a consequence of these features—deficient oxidation and slow elimination—the poison delays in the organism unduly long to continue its detrimental effects.

The fact that a portion of the nervous system—the optic nerve—is especially affected by methyl alcohol naturally suggests that this substance has a preferential affinity for the nervous tissue. Recent researches of Pohl[1] at the Pharmacologic Institute of the University of Breslau indicate that this suspicion is not verified. It almost seems, says Pohl, as if no organ retains so little methyl alcohol as does the brain. We must therefore assume that the nervous system is peculiarly sensitive to the toxic agent rather than that it is unduly overwhelmed by larger quantities concentrating in this tissue.

The prospect of effective treatment in the case of an agent exhibiting this peculiar behavior is not particularly promising. Pohl found in the case of animals poisoned with wood alcohol that a combination of bloodletting and injection of Ringer's solution seemed to decrease the concentration of the poison in vitally affected tissues. A similar result followed the introduction of charcoal subcutaneously into the body, this substance apparently serving to remove part of the unexcreted alcohol by specifically adsorbing it. Such procedures, interesting as they are in pointing the way to the possibilities of treatment, are far from practicable in the exigencies of human cases.

DENERVATED MUSCLE ATROPHY

When a motor nerve is severed, the muscle which it supplies enters into a state of inaction, so far as its usual contractile function is concerned, and muscular atrophy gradually ensues. Ultimately the nerve may regenerate so that a functional connection with its muscles again becomes restored. Obviously it would be of enormous physiologic advantage if the intervening muscular atrophy could be wholly or in part averted. Attempts at a successful therapy to prevent the disaster that follows the nerve injury and may be termed denervated muscle atrophy have not been wanting. The earliest efforts were based on the disuse theory—the belief that the wasting of the denervated muscle is due to the lack of exercise. Three quarters of a century ago in an experimental study of the problem, John Reid undertook to supply the supposedly needed activity by inducing contraction in denervated muscle by means of electrical stimulation; likewise the versatile Brown-Séquard attempted to avert the impending atrophy by the use of the galvanic current, which he assumed might not only keep up the muscle weight by the contractions induced, but also have some direct influence on the chemical changes similar to that produced by the nervous agent in the muscle. Evidently the vague "tropic" influence of the nerves on muscles was in the mind of the investigator. A recent review[2] of the situation in Brown-Séquard's time says:

> In man, the production of contraction in paralyzed muscles was not found to prevent atrophy, but it was generally thought to delay it. The theory was contested by many on the ground

[2] Langley, J. N., and Hashimoto, M.: Observations on the Atrophy of Denervated Muscle, J. Physiol. **52**: 42, 1918.

that the rate of loss of weight and the changes in the muscle after nerve section were of a different order from those occurring in disuse of the muscles arising from cerebral paralysis and from certain lesions of the spinal cord. On the other hand, it was argued that in these cases reflex and tonic contraction were not abolished, and the disuse only partial. Thus whilst, in general, disuse was held to account for a part only of the atrophy, the inactivity theory still had supporters.

Another theory subsequently unfolded led to the practice of massage and passive movement in cases of nerve severance in man. It was based on the observation that there is very little lymph flow in a normal quiescent muscle, and that the flow of the lymph is increased by movement. Here, then, seemed to lie a possibility for promoting the nutritive exchanges in an active muscle. In contrast to all of these views, Langley[3] of Cambridge, England, has suggested that the atrophy is due to the continuous fibrillation that occurs in a denervated muscle. Since certain salts, like those of calcium, are known to stop fibrillation, Langley and his co-workers have attempted to apply the fact to the treatment of denervated muscle. Feeding the salts having proved impracticable or of no avail, ionization schemes by means of electric currents have been attempted. The practical difficulties of this plan are almost insuperable, since the currents required to stop the fibrillation in the deeper parts of the muscles are stronger than the skin will bear without undergoing abnormal changes.

After a trial, in an elaborate experimental way, of the various forms of treatment proposed, Langley and Hashimoto[2] have gained the general impression that none of the methods of treatment of denervated muscle now in use—passage of galvanic current, production of contraction, passive movements and massage—can have more than a slight effect in delaying muscle atrophy. The only direction of promise at present consists in continuing the time-consuming experiments on animals, in the hope of discovering new leads. As the Cambridge physiologists remark, the conditions in man allow of very little exact observation. The time of recovery, from six to ten months, varies so greatly with the unascertainable conditions at the point of suture that any influence there may be of other treatment is completely dwarfed. Connective tissue growth may easily be caused, and on that account measurement of the limbs at intervals of stimulation is a very insecure basis for estimating growth of muscle; moreover, if there were a growth of the muscle it would mean that the atrophy could be prevented altogether, and no one now, so far as we know, claims that this can be done.

The only remaining method in man is to compare the electrical irritability after the muscle has been left alone with that after it has been treated, a method by no means valueless, but one in which the experimental error is very large.

Current Comment

THE EFFECT OF INDUSTRIAL EMPLOYMENT ON MATERNITY

In the *Monthly Labor Review* for November, 1918, published by the Bureau of Labor Statistics of the United States Department of Labor, appears an abstract on the Effect of Industrial Employment of Women on Maternity. It is based on a report published by the Women's Industrial Council of London, in a recent issue of the *Women's Industrial News*. The problem undertaken was to discover, if possible, whether industrial employment affected a woman's capacity for successful maternity, and whether, if it did, it was due to industrial work per se, or to some particular kind of work. In order to secure authoritative information the investigation was confined to mothers under the care of some recognized authority, as schools for mothers, infant welfare centers, and maternity wards of hospitals. The first plans, including full particulars as to hygienic, occupational, domestic and personal conditions before marriage and before and during pregnancy, proved too ambitious, as practically none of the institutions kept sufficiently full records of the items involved to be able to contribute any valuable information. Only 934 cases were included in the study, so that the data available are not sufficient on which to base any definite conclusions. Some interesting observations, however, were made. As in many other health problems, the fact that most strongly impressed itself on the investigators was that practically no real data on the subject exist, and that the first step in any effort to solve the problem of the effect of employment on maternity is to acquire accurate knowledge of the influence of employment on the health of mothers and infants. Observation and the recording of facts must necessarily antedate marriage and pregnancy by a considerable period in order to form any sound basis of comparison. The inquiry into the effects of different kinds of employment also was unsatisfactory. A questionnaire sent to physicians, matrons and nurses at maternity hospitals, midwives, and visitors and superintendents of infant welfare centers produced the usual indefinite replies, based partly on fact and partly on prejudice or general impression. Such data as could be recorded and tabulated were also vague. Dividing the mothers according to whether they had or had not been industrially employed during pregnancy, it was found that the proportion of living children, children who had died, and stillbirths was almost the same for the two groups. Regarding the character of occupation, it was found that out of 331 mothers industrially employed during pregnancy, 213 employed in active occupations furnished eighty-three "bad" cases of labor, or 39 per cent.; eighty-eight women employed in sitting occupations furnished twenty-three "bad" cases, or 26 per cent., while thirty women employed in standing occupations furnished only two "bad" cases, or 6 per cent. "Bad" cases were defined as those in which (*a*) 25 per cent. or over of the children died; (*b*) the mother had a difficult or complicated confinement, or

---

[3] Langley, J. N.: J. Physiol. 50: 337, 1916.

(*c*) the infants born were not healthy. These figures, while interesting, are, as the investigators recognize, too few on which to base any definite conclusions. An interesting comment is made on the relative effect of industrial occupation versus domestic activity; attention is called to the fact that writers on infant mortality and the birth rate lay great emphasis on the evil of manual labor in factories, but say little if anything of the results of the incessant drudgery of domestic labor: "People forget that the unpaid labor of the working woman at the stove, at scrubbing and cleaning, at the washtub, at lifting and carrying heavy weights, is just as severe manual labor as many industrial operations in factories." The only definite conclusions by the investigators are that they are able to find no difference between domestic work and industrial work, nor any reason for prohibiting any woman from undertaking any kind of healthy employment of which she feels capable.

TETANY AND ALKALOSIS

To Wilson and his co-workers[1] at the Johns Hopkins Medical School belongs the credit of having directed attention to the possible physiologic and pathologic significance of alkalosis, a condition in which the equilibrium between acids and bases in the blood is displaced in favor of the bases. Alkalosis accordingly is the antithesis, so to speak, of the more familiar condition of acidosis. This abnormal preponderance of bases was described as the sequence of removal of the parathyroid organs, and makes its appearance with the onset of tetany. The latter can be relieved by the administration of acids with consequent restoration of the usual acid-base equilibrium in the organism. Furthermore, it is easy to believe that the tetany itself, leading to the production of acids through the muscular performances, will serve to relieve the condition of alkalosis and thus act as a corrective to the circumstances that initiate the tetanic outburst. At the Harvard Medical School, McCann[2] has verified the fundamental facts just referred to. His experiments in parathyroidectomy also show an increase in the ability of the plasma to combine carbon dioxid coincidently with the development of tetany. This may be interpreted as being due to an increase of the basic over the fixed acid radicals in the blood, as compared with that of normal animals. McCann has ventured further to consider the possibility of alkalosis in relation to gastric tetany. Experimentally he observed that, following operations on the stomach which exclude the acid secreted from the duodenum, tetany develops accompanied by an increase in the carbon dioxid combining power of the plasma similar to that of parathyroid tetany. Administration of acid intravenously or through the duodenum produced favorable responses toward more normal conditions. Various possibilities have been expressed in explanation of the mechanism by which the acid-base equilibrium may become displaced at times. Both the kidneys and the pulmonary ventilation may be concerned. McCann, however, has gone farther to interpret gastric tetany as a condition of alkalosis, in which a disproportion between the rates of secretion of acids and alkalis by the gastro-intestinal tract may be a factor. Clinically gastric tetany is most apt to occur, as McCann reminds us, in those cases in which there is some pyloric obstruction. The secretion of hydrochloric acid by the stomach, provided the acid does not pass into the duodenum to excite the alkaline intestinal secretions, might be expected to leave the blood with an excess of basic substances.

THE MILK SUPPLY IN ENGLAND AND IN AMERICA

If milk is really vital to national health and efficiency, it can well be understood why the United States Food Administration warns the American people to do everything to prevent in this country the tragic results that are following the cutting down of milk consumption abroad. To quote the words of the Food Guide,[1] it is *most unfortunate that ignorance of the value of milk makes people particularly sensitive to a change in its price. When it goes up even a cent a quart, many cut down their consumption, while a considerably larger advance in the price of meat will make little difference in the amount bought. That there is an actual decline in the use of milk in some of the large cities seems to be attested by statistics.*[2] Dr. Dorothy Reed Mendelhall[3] of the Children's Bureau, U. S. Department of Labor, has pointed out that in the United States the price of bread is controlled, while that of milk is not. Price fixing has its unforeseen difficulties that concern the indispensable producer on the one hand and the dependent consumer on the other. Mr. Hoover has asserted that obviously our people must have whatever food is necessary and must have it at prices that they can meet from their wage. If we are to have ascending prices, we must have ascending wages. But as the wage level rises with inequality, it is the door leading to strikes, disorder, riots, and defeat of our national efficiency. We are thus between two fires—to control prices or to readjust the income of the whole community. The verdict of the whole of the world's experience is in favor of price control as the lesser evil. We shall not venture any opinion as to what can be done in the area of commerce between the producer and the retailer. In England a milk order empowered the local authorities to arrange for the supply of food and milk to the "priority" class of mothers and children; and according to Dr. Mendenhall they were permitted to obtain it at a low price, the deficit incurred being charged to grants for maternity and child welfare. In this country we have obtained bread at low prices without the subsidy that was found necessary in England. Perhaps milk also can be kept within purchasable range for all by some sort of voluntary agreement, such as Mr. Hoover has so judiciously brought about in other instances. But whatever may be the device needed, let us not only conserve our dairy herds and enhance the milk supply, but also make certain that it becomes available to the children of America.

CAUSE OF DENTAL CARIES

Although considerable difference of opinion exists with regard to the influence exerted by oral sepsis on the general health, there is no disagreement as to the harmfulness of dental caries. There may be skepticism regarding the statements of well known medical practitioners that oral sepsis is the *fons et origo* of the majority of systemic diseases, but there can be no denial of the fact that dental caries is a serious condition, tending to ill health. The inability to masticate food properly when dental caries is present is sufficient in itself to demonstrate this. When a person cannot chew food thoroughly, digestive disturbances may occur not infrequently. It is generally supposed that people leading a primitive life suffer little with their teeth. This is true to a large extent. However, even natives of Africa living in a cleanly, natural manner are by no means immune to dental caries. Dr. Stannus[1] examined the entire population of a series of villages in the West Nyasa District of Nyasaland. Their diet was chiefly cassava made into porridge and some eaten raw, other constituents being ground nuts, fish, a little maize or millet, flour porridge, green vegetables and bananas. Of 1,311 persons examined, 1,038 of whom were adults, 8.6 per cent. showed caries. Stannus concluded that native Africans have no immunity to dental caries, and that the same causes and predisposing conditions are the source of caries among them as among people of civilized countries. The small comparative incidence of caries among natives living under natural conditions is due to the absence in large proportion of those predisposing conditions found in civilized races, irregular dentition, lack of proper mastication, and want of the use of the teeth, owing to the eating of soft foods. It has been urged by many that one of the main causes of dental caries is the eating of food that requires little mastication, and that consequently dental caries has increased greatly because in civilized countries so much soft food is consumed. Dr. Harry Campbell of London may be termed the high prophet of this propaganda, and he preaches in and out of season of the injury to the teeth and to the health done by eating "pappy" food. The teeth were intended to be freely used in the mastication of hard food. When they are not so used they tend to decay, and the general health suffers.

Hygiene and the State.—The health laws of the state to be effective must be supported by a people trained to understand and trained to obey these laws. The hygiene of the state as a whole cannot be better than the hygiene of the people who make the state. An effective physical training of the individual is then a contribution in the service of the state.—T. A. Storey, M.D., Ph.D., on Physical Training.

Medical Mobilization and the War

Personnel of the Medical Department

For the week ending January 24 there were in the Medical Corps of the Army 24,348 officers, a decrease since the previous week of 523. By rank there were two major-generals, six brigadier-generals, 223 colonels, 481 lieutenant-colonels, 2,331 majors, 8,473 captains and 12,832 first lieutenants. In the Medical Reserve Corps there are now 626 officers. Discharges since the beginning of the war include 9,263 officers.

Weekly Bulletin A. E. F.

Weekly Bulletin No. 39 of the American Expeditionary Forces, dated Jan. 6, 1919, gives a summary of certain communicable diseases in the A. E. F. during 1918. There were 30 cases of anthrax, almost all traced directly to shaving brushes. There were 185 cases of chickenpox; 3,456 cases of diphtheria; 863 cases of amebic and bacillary dysentery of proved type; 5,953 cases of measles, with a monthly rate per 100,000 varying from 14.4 in February, 1918, to 358 in January, 1919. There were 1,469 cases of meningococcus meningitis and 1,460 cases of scarlet fever. There were nine cases of smallpox and 579 cases of typhoid fever and paratyphoid fever. The monthly rate for typhoid and paratyphoid varied from 0.0 cases in February, 1918, to 11.1 cases in July, 1918. Most of the cases occurred in two small epidemics and in scattered cases following the Argonne offensive. The weekly review states that typhoid is still increasing, and that more new cases of typhoid than of any other of the communicable diseases have been reported during the past week. Diphtheria, measles, meningitis and scarlet fever show a reduction since the previous week.

HONORABLE DISCHARGES, MEDICAL CORPS, U. S. ARMY

Note.—In the following list, L., signifies lieutenant; C., captain; M., major; L. C., lieutenant-colonel, and Col., colonel.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST; SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION, PUBLIC HEALTH, ETC.)

ARKANSAS

Personal.—Dr. James M. Boyd, Ravana, was appointed acting assistant surgeon, U. S. P. H. S., Oct. 18, 1918, and sent to Foreman for relief work in the influenza outbreak, and from there to Little Rock, Conway and Yell counties.——Drs. Cyrus F. Crosby, Heber Springs, and Hercules R. Webster, Texarkana, have been appointed members of the state board of health for a period of four years.

COLORADO

Personal.—Dr. William M. Moore, LaJunta, is reported to be seriously ill in Orlando, Fla.——In the case of Dr. Bennett Graff, Denver, recently convicted of causing the death of Mrs. Ruth Camp, through an illegal operation, the judgment was reversed by the supreme court, January 6.——Dr. Livingston Farrand, Boulder, president of the University of Colorado, has been made an officer of the Legion of Honor in recognition of his work as head of the Rockefeller Anti-Tuberculosis Commission to France.——Dr. William A. Kickland, Fort Collins, who has been seriously ill with pneumonia, is reported to be improving.——Dr. Edward P. Hummel, Sterling, has been elected president of the Northeastern Colorado Medical Association.

CONNECTICUT

Personal.—Dr. William M. Stockwell has been appointed superintendent of health of Hartford.——Dr. Frederick E. Wilcox, Willimantic, has been appointed medical examiner (coroner) for the towns of Hampton, Chaplin, Windham and Scotland.

New Officers.—The Connecticut Society of Social Hygiene held its eighth annual meeting in the rooms of the Hartford Medical Society, Dec. 18, 1918, and elected the following officers: president, Prof. Charles A. E. Winslow, New Haven (reelected); secretary, Dr. Thomas N. Hepburn, Hartford, and treasurer, Mrs. Josephine B. Bennett, Hartford.

ILLINOIS

Personal.—Dr. Ola A. Kibler, for several years head physician at the State Home for Boys, St. Charles, has resigned to accept a similar position in Milwaukee, and Dr. W. E. Weisman of the State School for the Feebleminded, Lincoln, has been appointed to fill the vacancy.

Sanatorium Soon to Open.—The LaSalle County Tuberculosis Sanatorium at South Ottawa will be formally opened to the public, February 2. Exercises will include addresses by Dr. Kimball W. Leland, Utica, president of the sanatorium board; Dr. George Thomas Palmer, Springfield, president of the Illinois Tuberculosis Association; Dr. C. St. Clair Drake, Springfield, director of the state department of public health; Dr. David R. Lyman, president of the National Tuberculosis Association, and Dr. Hugh M. Orr, LaSalle.

Physician's License Revoked.—The license of Dr. W. J. Crozier to practice medicine and surgery in all their branches in the state of Illinois was revoked by the Department of Registration and Education of Illinois on Saturday, Jan. 18, 1919, for the following specific charges: (*a*) That he has advertised under a name other than his own. (*b*) That he has by false or fraudulent representation obtained or sought to obtain practice in his profession. (*c*) That he has by false or fraudulent representation of his profession obtained or sought to obtain money or any other things of value.

Chicago

Polish Society Elects Officers.—At the annual meeting of the Chicago Polish Medical Society, held, Dec. 30, 1918, the following officers were elected: president, Dr. Wladyslaw A. Kuflewski; vice president, Dr. Marie T. O. Kaczorowski; treasurer, Dr. Francis F. Wisniewski, and secretary, Dr. Michael C. Goy.

Personal.—Casey A. Wood, Lieut.-Col., M. C., U. S. Army, has gone to San Diego, and after a visit there will go to the Leland Stanford, Jr., University for several months of special work.——Capt. H. I. Davis, A. R. C., is chief of the neurologic service in the American Red Cross Evacuation Hospital No. 3, located at Trier in Germany.

Irregular Practitioners Fined.—Mr. W. M. Hayes of 3813 State Street, according to his own statement, a "Divine Healer," was arrested by the Department of Registration and Education of the State of Illinois for violating the Medical Practice Act, and fined $100 by Judge Caverly of the Municipal Court of Chicago. When an inspector of the department called on the "Divine Healer," he diagnosed his ailment and said he could cure him by prayer. He took the right hand of the inspector in his hand, laid his left on the inspector's head and offered a prayer, at the conclusion of which he pronounced the inspector cured and demanded $3. The inspector told him he had but $1 and the "Divine Healer" took that in full payment for his services. Within a few hours he was arrested.——Mr. L. W. Miller, a chiropractor at 1705 West Madison Street, was arrested by the department for violating the Medical Practice Act. He was fined $25 and costs for practicing without a license.——Mr. Grant E. Mitchell, an osteopath at 5228 Ellis Avenue, was arrested by the department, and was fined $25 and costs for practicing without a license, in violation of the Medical Practice Act.

MARYLAND

Back from France.—Drs. Hugh H. Young and Dr. Francis X. Kearney, both of Baltimore, have returned from France. Dr. Kearney has resumed his position as superintendent of Mercy Hospital.

New Officers.—Baltimore County Medical Society at its annual meeting, January 15, elected Dr. Frank W. Keating, Owings Mills, president; Dr. John W. Harrison, Middleriver, vice president, and Dr. Alfred T. Gundry, Catonsville, secretary-treasurer.——Talbot County Medical Society at its annual meeting, held at Easton, Dec. 30, 1918, elected the following officers: president, Dr. Edward R. Trippe, Easton; vice president, Dr. James B. Merritt, Jr., Easton, and secretary-treasurer, Dr. Joseph A. Ross, Trappe.

Child Hygiene Bureau Established.—Dr. Mary Sherwood, Baltimore, has been named as the chief of the bureau of child hygiene to be established at the health department. Her assistant will be Dr. Mary Cook Willis. The appointments were announced by the mayor at the conclusion of a conference with Health Commissioner Blake and Drs. William H. Welch, J. H. Mason Knox, Jr., John Howland, John Ruhräh, James M. H. Rowland, Grover F. Powers, William T. Howard, Jr., and John F. Hogan, all of Baltimore. Dr. Mary Sherwood was asked to make a report as to the scope of the work which is to be started this year, out of an appropriation of $30,000 made by the board of estimates.

Increase in Influenza Cases.—With 300 new cases in Baltimore and 1,048 in the counties, influenza established, January 23, a record that has not been equalled since the height of the epidemic last fall. Health Commissioner Blake called a meeting of his advisory board and discussed with them the situation as it has been reported to him by the health wardens, public health nurses and by physicians in private practice. The discussion resulted in the unanimous opinion that all was being done that the exigencies of the case demanded and that better results could not be obtained by more drastic measures which the board felt entirely unnecessary at this time. Of the 1,048 cases reported to the state department of health, 483 came from Allegany County, many of them doubtless carried over from the epidemic period. Reports of 232 new cases came from Dorchester County, which represent actual conditions in that part of the state.

Personal.—Brig.-Gen. John M. T. Finney, Baltimore, chief consulting surgeon of the American Expeditionary Forces, who sailed nineteen months ago for France as head of the John Hopkins Base Hospital Unit, returned to the United States aboard the *Melita*, January 22.——Lieut. Samuel J. Price, Queenstown, who went to France early in 1918, has returned to his home in Centerville. He sustained wounds from shrapnel in the right leg and also was in the hospital for some time suffering from gas poisoning.——Capt. George L. Stickney, who has been in France since May, 1917, serving with the American forces in the Toul sector, is expected to arrive in this country at an early date. Captain Stickney was wounded at Soissons, July 18, and was under treatment in a hospital for three months. Later he was assigned to duty at the American Base Hospital at Autun.——Dr. Jules Duesberg, the Belgian scientist, will sever his connections as a member of the faculty of the Johns Hopkins University and sail for Belgium on February 12. Dr. Duesberg came to Baltimore in 1915. He is a native of Liege and received his degree as doctor of medicine at Liege University in 1905. In 1906 he went to Kiel, Germany, to take up anatomic research work, and in 1911 was made professor of anatomy at the Liege University, where he will now resume his work. ——Dr. Harry S. Jarrett of Towson, who has been under treatment at the Mercy Hospital, Baltimore, is convalescing at Atlantic City, N. J.——Dr. Joshua Rosett of Baltimore has been under director of an expedition sent out by the Red Cross from Vladivostok to combat a threatened epidemic of typhus in Siberia.

MASSACHUSETTS

Personal.—Dr. Wilfred E. Rounseville has been appointed city physician of Attleboro.——Major David D. Scannell, M. C., U. S. Army, Jamaica Plain, has returned after nearly six months' service in command of American Hospital No. 7, American Expeditionary Forces, Tours, France.——Dr. Albert S. Hyman, Boston, has been appointed assistant resident physician to the Long Island Hospital, and Charles M. Flagg, assistant medical advisor of the Consumptive Hospital, Boston.——Dr. Anngenette Fowler-Noble has been elected president of the Westfield Visiting Nurse Association.

Industrial Health Board Named.—President Lowell and Fellows of Harvard University have appointed the following committee to work in conjunction with members of the course in industrial health recently established at the University to extend similar work to mercantile establishments: George W. Mitton, president of the Jordan-Marsh Company; F. Alexander Chandler, president of the Chandler-Farquhar Company; Thomas H. Cory, vice president of the William Filene's Sons Company; George E. Johnson, president of the R. H. White Company; Robert H. Maynard vice president of the R. H. Stearns Company; Felix Vorenberg, vice president and secretary of the Gilchrist Company, and Thomas M. B. Hicks, Jr., secretary. The committee announces that the sum of $50,000 to finance the project will be obtained. The probable scope of the committee includes an investigation into the character of health supervision of mercantile employees in large cities of the United States; an analysis on the basis of this investigation of the best methods of safeguarding the health of such employees; a listing of the complaints which are standard causes for lost time on the part of the mercantile employees; the analysis of the extent to which tuberculosis, venereal disease and other serious conditions, existing in retail stores, and the development of a system of health education for store employees.

NEW YORK

Committee Enlarges Scope.—At the meeting of the executive committee of the Rochester Tuberculosis Committee, held January 16, it was proposed to recommend that the name of the organization be changed to The Tuberculosis Association of Rochester and Monroe County.

Amendment to Sanitary Code.—At a meeting of the public health council of the state department of health, Dec. 4, 1918, Regulation 36 of Chapter II of the Sanitary Code relating to the minimum isolation period for measles was amended to read as follows: "Measles, until at least five days after the appearance of the rash."

Personal.—Dr. John D. Howland, Buffalo, resumed, January 16, his duties as superintendent of the Erie County Hospital which were interrupted by his absence overseas on military service.——Dr. George S. Staniland, Buffalo, has been appointed temporary acting health commissioner during the illness of Acting Health Commissioner Gram.

New York City

Personal.—Dr. Henry Dwight Chapin has been appointed chairman of the Public Health Subcommittee of Governor Smith's Reconstruction Committee formed to solve postwar problems.——Dr. Bernard Sachs has been elested president of the medical board of Mount Sinai Hospital, to succeed Dr. Abraham Jacobi, who has resigned after thirty-five years of active service.

Women Give Hospital to Roosevelt Memorial Expedition.—The Aviation Committee of the National Special Aid Society has voted to contribute the complete hospital equipment and supplies for the Roosevelt Memorial Arctic Expedition which is to start by airplane for the Polar regions in June of this year.

Health Commissioner Copeland Starts New Plan.—Dr. Royal S. Copeland announced, January 25, that he had appointed Dr. S. Dana Hubbard to start the work of the division of industrial hygiene under the new plan which separates this division from the bureau of preventable diseases of which Dr. Louis I. Harris is director.

Influenza Again Increases.—During the sixteenth week of the influenza outbreak in this city, ending January 25, there has been a steadily mounting number of cases recorded each day, until, for January 24, there were 672 new cases reported. This renewed outbreak of the epidemic has caused Health Commissioner Copeland to request the police to again distribute circulars containing suggestions as to how a recurrence of the epidemic may be avoided.

Organizations Endorse Health Bill.—At a meeting of the council of organizations, representing between 400 and 500 bodies in New York, January 24, ways of meeting the present health emergency were discussed, and resolutions were passed approving the Rankin-Robinson bill now before Congress, which has for its aim the preservation of all the bureaus of industrial hygiene. It was the consensus of opinion that it was highly important that matters pertaining to public health be brought to the attention of Congress for proper legislative action, especially infant hygiene. The council of organizations also put itself on record as protesting against the action of Health Commissioner Royal S. Copeland in removing the division of industrial hygiene from the bureau of preventable diseases.

OHIO

State Association Meeting.—The Ohio State Medical Association announces it will hold its seventy-fourth annual meeting in Columbus, May 6 to 8.

License Revoked.—The license of Dr. Levi W. Hunt, Toledo, is said to have been revoked by the state medical board, January 10. Dr. Hunt is said to have been charged with exaggerated advertising.

Legislative Measures for Health Reform.—On the recommendation of a commission to investigate the desirability of compulsory health insurance for Ohio a bill for the reorganization of the health service of the state will soon be presented in the legislature substituting for the present plan of village, township and city boards of health a system making the county or other larger district the local administrative unit. This plan is advocated by Governor Cox. The health insurance commission has also urged legislation providing for physical supervision of pupils in all Ohio schools.

For Public Health Nurses.—Under a bill recently passed as an emergency measure by the state legislature, city boards of health in Ohio will be empowered to employ public health nurses in such numbers as it may deem necessary, subject to the limitation that the city council may fix the maximum number. The bill has special importance in connection with the influenza epidemic. Its effectiveness during present and future epidemics will be limited somewhat, perhaps by the requirement that the nurses employed shall be registered nurses, a feature that has received some criticism in view of the difficulty of procuring nurses during the influenza epidemic, on account of shortage in the supply.

Personal.—Dr. Harry L. Rockwood, head of the tuberculosis sanatorium at Warrensville, is acting temporary health commissioner of Cleveland, succeeding Dr. Robert H. Bishop, Jr., who has resigned to accept a position as assistant director of the American Red Cross Antituberculosis Unit in Italy.——Dr. Louis G. Knowlton, Cleveland, was cut and bruised about the head in a collision between his automobile and an interurban car, near Berea.——Dr. Robert S. Barton, New Philadelphia, announces his retirement after twenty years of practice.——J. M. Ernst, Massillon, is said to have pleaded guilty to furnishing and selling morphin illegally, and to have been fined $50 and costs on each of two charges, January 7.——Dr. Henry W. Lehrer has succeeded Dr. Fred Schoepfle, Jr., as coroner of Erie County.——Dr. Addison D. Hobart, Toledo, has been held to the grand jury under bond of $2,500 on the charge of unlawfully dealing in narcotics.

PENNSYLVANIA

Personal.—Capt. J. Frederick Wagner, Bristol, has been made a major, having been cited for bravery in action in a battle north of L'Homme Mort, when he saved the life of a wounded American soldier at the risk of his own life.

Society Plans Permanent Home.—At the annual banquet of the Lehigh County Medical Society in Allentown, January 14, a campaign for funds for a permanent home for the society was inaugurated. It is reported that $5,000 were subscribed for the home on this occasion.

Election of Officers.—The Somerset County Medical Society met in Rockwood for the election of officers and the following were elected: president, Dr. George F. Speicher, Rockwood; vice president, Dr. Albert M. Lichty, Salisbury; treasurer, Dr. Carl W. Frantz, Confluence, and secretary, Dr. Henry C. McKinley, Meyersdale.

Held for Violation of Drug Act.—Dr. Charles A. Lanon, Brownsville, is reported to be held under $3,000 bail for alleged violation of the Harrison Narcotic Law.——Dr. John C. Bateson, Scranton, who pleaded nolle contendere to a charge of selling habit forming drugs to addicts, is said to have been fined $500, January 20.

Influenza at Chester.—Dr. Harry C. Donahoo, supervisor of the Chester Department of Health, issued a bulletin, January 25, urging the cooperation of the citizens in stopping the spread of influenza and asking all nurses in the city to register at the City Hall, that they may be called in an emergency. There are from 500 to 600 cases in the city.

Pennsylvania Medical Officers Reported Wounded.—Lieut. Sloan A. Brown, M. C., U. S. Army, Coraopolis, slightly; Lieut. Charles C. Ryan, M. C., U. S. Army, Republic, severely; Lieut. J. Armin Stackhouse, M. C., U. S. Army, Ambler, degree undetermined; Lieut. Lloyd E. Wurster, M. C., U. S. Army, Philadelphia, severely.——Dr. James P. H. Ruddy, Scranton, on duty with the American Expeditionary Forces in France, has been gassed.

Personal.—Elmer A. D. Clarke and Frank L. Martine, lieutenants, M. C., U. S. Army, Bethlehem, were each given a gold watch by the president of the Bethlehem Steel Company in appreciation of their services rendered the hospital of the Northampton house, during the recent epidemic of influenza.——Dr. W. W. Serrill, Kellettville, sustained a fracture of the right leg and other injuries by the overturning of his automobile near Kellettville, January 17. Dr. Serrill was pinned under his automobile for twenty-one hours before he was discovered.——Dr. Harvey M. Becker, Sunbury, associate in the eye, ear, nose and throat department of the George F. Giesinger Memorial Hospital, Danville, resigned, January 14.

Philadelphia

New Entrance Test for University.—Following the example of Columbia University, the University of Pennsylvania intends to institute psychology or intelligence tests to replace the old fashion admission examinations. The test will be similar to those applied to applicants for the Army Training Corps.

Personal.—Dr. John D. McLean, recently appointed assistant commissioner of health, assumed charge of the department, January 3, in the absence of Dr. Edward Martin.——Dr. Charles J. Hatfield succeeds Mr. E. T. Stotesbury as chairman of the Southeastern Pennsylvania Chapter of the American Red Cross.——Dr. George M. Lipeviski has been appointed outdoor physician, bureau of charities.

Epidemic Influenza.—In spite of efforts of the health officials, influenza continues in epidemic form. For the twenty-four hours ending at noon, January 25, 154 new cases had been reported by physicians as compared with 158 cases returned the previous day. During the week ending at noon, January 24, 792 cases of influenza and 267 cases of pneumonia were returned which was an increase of 175 in influenza and a decrease of twelve in pneumonia as compared with the reports for the preceding week.

WASHINGTON

State Board Election.—At a recent meeting of the state board of medical examiners of Washington, Dr. Andrew J. Nelson of Seattle was elected president; Dr. J. E. Hodgson, Spokane, vice president; Dr. Royal A. Gove, Tacoma, treasurer, and Dr. Conrad N. Suttner, Spokane, secretary. There is a vacancy on the board occasioned by the death, in December, of Dr. Elmer D. Olmstead, Spokane.

Personal.—Dr. John B. Anderson has been reelected health officer of Spokane for the ninth time.——Dr. Waldo Richardson, Seattle, was chief surgeon of the steamship, *Northern Pacific*, the Army transport which was recently aground off Fire Island, near New York.——Dr. Carrie A. Benefiel, Spokane, is ill with pneumonia.——Dr. Jerry E. VanderPool has resigned as city and county health officer of Walla Walla County.

WISCONSIN

Residence Given for Nurses' Home.—Mr. and Mrs. Henry Gund, LaCrosse, have given their home, representing a cost of $25,000, completely equipped and furnished as a nurses' home to the LaCrosse Hospital, to be known as the Eleanor Gund Nurses' Home.

Hospital News.—The Ashland General Hospital is enclosed, [illegible] and is now almost ready for equipment. [illegible] Hospital established in Garfield School, Washburn, during the influenza epidemic, has been closed.——Ashland, Bayfield, and Iron counties have appropriated $80,000 toward the Tri-County Tuberculosis Sanatorium to be built near Salmo.

New Plan of Health Administration.—Dr. John J. McGovern, Milwaukee, has worked out a plan for health administration in the state providing for a state health department to take the place of the present board of health with a state commissioner of health appointed by the governor and confirmed by the senate, and assistants to be selected from the civil service lists.

Elections.—At the annual meeting of the Milwaukee Medical Society, January 14, Dr. Hoyt E. Dearholt was elected president, Dr. David E. W. Wenstrand and Alfred L. Kastner were elected vice presidents, Dr. Oscar Lotz was elected secretary, and Dr. Joseph P. McMahon treasurer, all of Milwaukee.——At the annual meeting of the Milwaukee Hygienic Society, January 10, the following physicians were elected to office: president, Dr. George C. Ruhland; vice presidents, Drs. George A. Harlow and Philip F. Rogers, and secretary, Dr. John Vande Erve.——At the annual meeting of the Council of the State Medical Society of Wisconsin, held in Milwaukee, January 13, Dr. Edward Evans, LaCrosse, was elected chairman, Dr. L. Rock Sleyster, Waupun, secretary, and Dr. Sidney S. Hall, Ripon, treasurer. The council discussed a number of legislative measures concerning the more complete restriction of communicable diseases. One of these proposes to extend the period of compulsory quarantine for scarlet fever from three to five weeks.

Personal.—Dr. Calvin F. Hess, Madison, charged with malpractice in the performance of a mastoid operation, was cleared in the trial, January 15.——Dr. Frank H. Turner, Frederic, is reported to have pleaded guilty to sending various messages reporting the illness of relatives of soldiers in order that they may obtain furloughs, and to have been fined $1,000 by the Federal [illegible] January 11.——Dr. Ira F. Thompson, Eau Claire, has resigned after six months leave of absence from his position as deputy state health officer, and will enter at once on his new duties as organizer and director of the social hygiene department of the state.——Dr. Chester M. Echols was elected president, Dr. William F. Wegge, vice president, and Dr. Oscar Lotz, secretary, all of Milwaukee, of the medical staff of Emergency Hospital, Milwaukee, January 1.——Dr. William A. Prouty, Burlington, is reported to be seriously ill in a hospital at Jacksonville, Fla.——Dr. George F. Hilton, Sturgeon Bay, was seriously burned about the face and hands by a gas explosion in his furnace recently.

CANADA

Personal.—Major Brefney R. O'Reilly, M.D., Toronto, chief medical officer of the Royal Air Force in Canada, has been made a member of the Order of the British Empire.——Col. Herbert S. Birkett, Montreal, who recently returned overseas to take up a short course of duties with the Medical Service, has been appointed chief assistant to the director of medical services in the Canadian Army.——Dr. Henry Crassweller, Windsor, Ont., has returned after three years' service overseas. He was part of the time a prisoner in Cologne and Hanover, and for a time worked in a German hospital at Lecateau.——Major Samuel Harvey McCoy, Toronto, who has done excellent work in various capacities in England, is reported ill.

Board of Health on Influenza.—The board of health of Ontario, with a view of learning the experience of provincial and state medical officers of health in influenza, addressed the following letter of inquiry: "Does your province (or state) require the reporting, placarding, and quarantine of influenza, and, if so, do you consider placarding and quarantine of such, practicable?" Replies were received from nine officers of health in Canada and from forty-three state officers of health. Four of the provinces of Canada found placarding and quarantine were impracticable. One states that modified quarantine was working well; another, that the law was not well obeyed; a third, that it was almost impossible in rural places; a fourth, that there were many infractions but of good effect; a single officer declared it of good effect. Of the reports from the United States, twenty-nine out of forty-three, or 67 per cent., stated that placarding and quarantine in influenza were impracticable. Of the remainder of the replies nine report the law practicable, and five qualified their statements as follows: "seems to be of value"; "enforcement depends on local sentiment"; "law fairly well obeyed"; "beneficial"; "believe quarantine should be included." Out of fifty-two officers of health, state and provincial, nine frankly state, as a result of their experience, that placarding and quarantine are practicable, ten qualify their approval and thirty-three frankly state that these measures are impracticable.

GENERAL

Lieutenant-Colonel de Tarnowsky to Head Relief Work in Serbia.—Lieut.-Col. George de Tarnowsky, Chicago, has been given charge of medical relief work in Serbia with a staff of officers selected by him from the Medical Corps of the United States Army. Because of a shortage of physicians the relief work in Serbia will be of a medical character differing in this respect from similar work in Roumania.

Rural Hygiene.—Representatives of the state boards of health of Indiana, Michigan, Illinois, New York, Massachusetts, North Carolina, South Carolina, Minnesota, Kansas and Washington appeared before the committee on agriculture of the House of Representative in Washington, January 16, to present arguments in favor of the bill pending before the house, which contains provisions for a program to benefit rural health, involving an appropriation of $1,000,000.

Health Sunday.—Surg.-Gen. Rupert Blue, U. S. P. H. S., who appealed through a proclamation to clergymen of the country to set aside February 9 to preach sermons emphasizing the responsibility of the nation to protect the returned soldiers and sailors and communities at large, requesting also that there be inaugurated vigorous measures for the combating of venereal diseases, has announced that Health Sunday has been postponed from February 9 to 23, so as not to conflict with the Theodore Roosevelt memorial services, arranged for the former date.

Medical Relief in the Balkan States.—Major Roger D. Perkins, Cleveland, who has been in Paris for some time as medical liaison officer for the National Research Council, has joined the Balkan commission as director of public health and sanitation. He will make a tour of inspection through the Balkan states to advise with the various Balkan governments as to needs in this field. It will be remembered that Major Perkins accompanied the original Red Cross commission for relief in Roumania. A description of the work of the first commission appears in an article published in The Journal by Lieut.-Col. H. G. Wells and Major R. D. Perkins, March 16, 1918.

Commission to Roumania.—Lieut.-Col. H. Gideon Wells, Chicago, left the United States early in November as a member of the Balkan commission of the American Red Cross. The armistice and the cessation of hostilities made necessary a change in plans. He has now been detached from the position in connection with the commission to the Balkan states, and has been appointed commissioner representing the Red Cross in Roumania. He has organized a commission of sixty-eight persons to undertake general relief work instead of medical relief work alone, as there is a well developed medical profession in Roumania. The medical men of the party, aside from Lieutenant-Colonel Wells, are Lieut.-Col. Morley D. McNeal of Johns Hopkins, Baltimore, and Major J. Breckenridge Bayne, Washington, D. C. The latter was two years in Roumania, kept there practically as a prisoner during the German occupation, although allowed to do medical work among the Roumanian people. The work promises to be both interesting and practical because it is reported the Bolsheviki are making strong efforts to secure a foothold in Roumania, working from both Russia and Hungary. Abundant medical supplies will be taken to equip Roumanian physicians and hospitals.

FOREIGN

Spanish Hospital at Rome.—The two sons of a Spaniard, Sr. J. Taya, have given the Italian Red Cross $100,000 to found a fifty bed hospital at Rome, to be used for sick and wounded soldiers at first. Two years after the conclusion of peace, half the beds are to be reserved for the members of the Spanish colony in Italy.

Influenza in Pago Pago.—From Pago Pago, American Samoa, January 6, it was reported that communication between the island of American Samoa and Western Samoa was still cut off on account of the influenza epidemic. It was said that in Western Samoa one third of the population had succumbed to the disease.

Casualties in the Profession in Germany.—The *Nederlandsch Tijdschrift* cites some figures from Germany to the effect that the 1,200 casualty lists published by the German army and navy contained the names of 1,158 physicians reported as slightly wounded, 332 severely wounded, 663 killed, 422 as succumbing to disease, 212 taken prisoner, seventy-two missing and one killed by gas.

The University of Ghent.—Dr. Léon Fréderieq was professor of physiology at Liége and later at Ghent. He was imprisoned by the Germans because he refused to continue his courses in Flemish after the Germans had taken the city and were trying to remodel the university to be a Flemish institution. The government of Belgium has now appointed Professor Fréderieq lord rector of the university.

Personal.—Prof. H. Burger of Amsterdam has been elected corresponding member of the laryngologic section of the Royal Society of Medicine at London.——Prof. J. Rotgans of Amsterdam was given a sum of money, collected by subscription, on the recent twenty-fifth anniversity of his entering on the practice of medicine. He has donated the sum as the nucleus of a fund for cancer research in the Netherlands.

Italian Congress of Orthopedists.—The ninth annual meeting of the Italian Societá di Ortopedia, held at Milan in November, discussed the principles and practice of plastic motor surgery and expatiated on the importance of this kinematization of prostheses. The meeting adopted a resolution calling on the authorities to express in some way to G. Vanghetti, who was the originator of the idea of plastic motor operations and its apostle, the gratitude of science and of the Italian nation.

Netherlands Ambulance in Germany.—The Netherlands ambulance at Celle in Hanover continued for a long time after the signing of the armistice to have wounded soldiers sent there. The personnel has not met with any difficulties on account of the change of government. If possible, the *Nederlandsch Tijdschrift* remarks, they have been given greater appreciation. At the same time planned to return home in December as the cases are now becoming medical, while the ambulance is equipped only for surgical work.

Proposed Medical School at Khartoum.—The *British Medical Journal* states that the Gordon Memorial College, now in its seventeenth year at Khartoum, is doing fine work in spite of the European War cutting into its personnel. It is now proposed to found a medical school in connection as a memorial to Kitchener. About $45,000 has already been collected for the purpose in the Sudan, mainly by subscriptions from natives. Cerebrospinal meningitis was present in the Sudan last year. It is stated that owing to the difficulty of keeping guinea-pigs alive there, the Wassermann test could seldom be applied, but this difficulty has at last been overcome.

Deaths in the Profession Abroad.—Dr. **George Ogilvie**, on the staff of the Hospital for Epilepsy and Paralysis at London and writer on subjects connected with these specialties, F.R.C.P., senior physician to the French Hospital, aged 66. He had been decorated by the French, by the king of Italy and by the king of Portugal.——Dr. **Leonard G. Guthrie**, an eminent neurologist of London.—Dr. **O. Feijão**, professor of surgery at the University of Lisbon.—Dr. **S. Esquerdo**, director for forty years of the Carabanchel insane asylum, near Madrid, Spain.——Major **Miles Charles Cariston Seton**, Melbourne, Australia, M.B., C.M., 1900, University of Edinburgh, F.R.C.S., Edinburgh, 1908; who had served in South Africa in 1901; was shot and killed at the house of his cousin in England, January 13, by Lieut.-Col. Norman Cecil Rutherford, R. A. M. C. A verdict of willful murder against Colonel Rutherford was brought by the coroner's jury, January 24.

CORRECTION

Statistics of Baltimore.—We are informed by Dr. William H. Davis, chief statistician of the Bureau of the *Census*, relative to an item which apeared in The Journal, January 18, that the census department did not err in its statement as to the death rate of Baltimore, but that an error had occurred in the compilation of statistics in Baltimore. Dr. William T. Howard, Jr., assistant commissioner of health, has notified the department of the census that the error in compiling the statistics was made in the Baltimore Health Department.

SOUTH AND CENTRAL AMERICA, MEXICO AND WEST INDIES

Child Welfare Week at Buenos Aires.—Under the auspices of the Club de Madres a child welfare exhibition was opened at Buenos Aires in November. It is the second child welfare week that has been organized there.

Typhus at Santiago, Peru.—The *Revista de Beneficencia Publica* comments on the losses in the profession from the epidemic of typhus which is prevailing at present at Santiago and other cities of the republic. Dr. M. Guzman, intern at the Hospital de San Vicente, and Dr. C. Manterola, assistant in the Public Health Service, were among the victims in November, with four of the leading hospital nurses.

Lepers in Colombia.—The *Semana Medica* quotes from a recent official report at Bogotá, Colombia, to the effect that there is great room for improvement in the management of leprosy suspects. They are all conveyed to a detention laboratory where they are kept until the examiner comes, which is usually on Mondays. The diseased and the healthy are held here until the day of examination, as the authorities convey there, sometimes forcibly, any one who has been denounced as having leprosy. He may be taken by force from his home and without food or bed in which he can sleep, until the examiner finds it convenient to arrive. The appeal is made for a personal examination at the home, before sending the suspect to the detention laboratory for more thorough examination.

Compulsory Notification of Tuberculosis in Peru.—The Academia Nacional de Medicina at Lima has been discussing recently the feasibility of compulsory notification of tuberculosis. The general consensus of opinion seemed to be that a limited notification is practicable and useful, along the lines of the restricted compulsory declaration adopted in S. Paulo, Brazil. This provides for compulsory notification in all cases of deaths from this disease and when the sputum contains the specific bacilli and the subjects are in the following classes: (*a*) reside in neighboring house; (*b*) work in public offices, factories, and similar establishments; (*c*) are employed in eating houses, hotels, confectionery stores, cafés, groceries, etc.; (*d*) are employed as wetnurse, domestic servant, cook, laundress, scrubwoman; (*e*) are attending or teaching school. The academy voted in favor of the S. Paulo restricted compulsory notification. The discussion is given in full in the *Reforma Medica* of Lima.

BUENOS AIRES LETTER

Buenos Aires, Dec. 15, 1918.

Epidemics of Dysentery

The epidemics of dysentery at La Rioja and Catamarca have spread into the country. This renders much more difficult the campaign against this disease as the districts involved are poor with scanty resources.

Influenza in Paraguay

The influenza which spread from Buenos Aires to Paraguay acquired greater virulence there. The alarmed inhabitants believed that bubonic plague was responsible for the cases of death, but this assumption was disproved by Dr. Migone. Dr. Capurro, president of the Departamento de Higiene Argentino, has sent a commission to Paraguay to study the disease.

Entrance Examination for the Medical School

The notorious inadequacy of the preparation in physical and natural sciences has compelled the Facultad de Medicina to insist on an entrance examination. The diploma of the six years' course of studies at the Colegio Nacional Central will admit to the medical school without examination. Those completing the five year course will be obliged to undergo a written and an oral examination on botany, zoology, physics and chemistry.

Medical Botany to Be Dropped

The suppression of the course on medical botany seems to be imminent. The officials of the Facultad de Medicina are soon to decide the matter. In the meanwhile the first year students have decided not to enter for examination in this branch.

Medical School at Rosario

A new medical school is on the point of being inaugurated at Rosario. The building to house it is nearly completed, connected with the Hospital Centenario, and the courses are to be inaugurated in 1919.

Personal

Dr. B. A. Houssay, on the invitation of the Circulo Medico of Rosario, delivered an address before this society, November 20, on "Physiology of the Pituitary Body."

Dr. A. Bachsmann has been appointed chief of the section on entomology and medical zoology in the Departamento Nacional de Higiene.

PARIS LETTER

Paris, Dec. 19, 1918.

Disinfection of Wounds by Antiseptic Vapors

Dr. Lavenant of Paris recently reported to the Société de médecine de Paris a new method of disinfecting wounds by means of antiseptic vapors, first proposed by Dr. Le Faguays of La Roche-sur-Yon and which has yielded excellent results. The principle of the method is the disinfection of a wound by means of a current of gas charged with an antiseptic vapor. This current of gas may be ordinary air charged with an ether vapor to which a volatile antiseptic is added, such as phenol, camphor, oil of geranium. In some cases Le Faguays used air mixed with oxygen (half its volume) and saturated with ether vapor. A current of air is forced into a flask containing ether to which a volatile antiseptic has been added. Through the cork in the flask pass two tubes, one to admit the current of air, the other for the discharge of the medicated ether vapor. A Nelaton sound is passed down into the depths of the wound and is connected with the flask by a rubber tube. The antiseptic vapor is thus brought into contact with the wound surface. The treatment is continuous, day and night. Results are obtained quickly. The infected wound is usually cleaned up in twenty-four or forty-eight hours at the most, even when the infection has resisted the usual methods of treatment of infected wounds. The time required to produce similar results with other methods of treatment is about ten days. The expense of this treatment is slight and the patient is not being worn out and discommoded by having his bed saturated with irrigating fluid, as is the case when continuous flushing is employed.

Light Surgical Automobile Unit

At a recent meeting of the Société de chirurgie de Paris, Dr. Guillaume-Louis of Tours described a sort of flying surgical automobile unit intended to give service to wounded soldiers who are not transportable (such as cases of wounds of abdomen, thorax, head or extremities) during troop movements. The plan was first proposed by Professor Jeanbrau. The unit consists of two motor lorries convoying two two-wheeled carts and two small trucks. These light vehicles can travel over all roads without getting stuck. The lorries carry an operating room. On one of the two carts is placed the roentgenographic apparatus and on the other the sterilizing outfit. One of the small trucks contains the remainder of the surgical apparatus (instruments, laboratory equipment, etc.) and the material to form the closed-in archways between the various tents; the other truck carries the clothing of the personnel and can be used also to carry provisions for the group. This unit does not carry any tents or beds which could be used for hospital purposes, because these would add too much weight to the outfit, and it is preferable therefore, to depend on the front line for this hospitalization.

The Mentality of the Female Worker

At a recent meeting of the Académie des Sciences, Dr. Amar showed that sustained mental effort, concentration, in short, the will power of women workers is manifestly inferior to that of men workers. This is notably manifested in the yield or production resulting from the lesser occupations, but of a more or less mental nature, that is, requiring some "brain" work, such as adding columns of figures, copying letters, counting and wrapping pills or pins, sorting pens and verifying the good quality of the point. Amar has determined, with an electrical contrivance, that a sort of auditory or visual rhythm promotes the cerebral activity of women. He has reached the conclusion that the motor reactions of women always obey an auditory or visual rhythm. In the performance of all delicate work, work necessitating rapid movement, there exists for the ear as well as for the eye a proper cadence which lessens fatigue and increases production. Continuous labor, even with a perfect cadence, demands constant attention, with the result, so far as women are concerned, that respiration becomes modified and fatigue occurs earlier; even anemia and neurasthenia may result. All things being equal, the sensibilities of women are more affected by outside influences. Hence, women are emotional, full of sympathy—and likewise subject to antipathies—and these characteristics rule the mental processes of the woman worker.

Establishment of a Social Hygiene Dispensary

The general council of the department of the Seine has decided to establish a social hygiene and anti-tuberculosis dispensary to be known as the "Office publique d'hygiène sociale."

War Welfare Work

The "Secours de guerre" recently held a general meeting at which the secretary-general explained the activities of this group of workers, which are directed toward assisting the soldiers on furlough whose homes are in the invaded parts of France or who are without family, as also all refugees and repatriates. Since 1914, the Secours de guerre has hospitalized 1,697,884 refugees; during the time of the German drive on the Chemin des Dames, during twelve nights, there were sheltered, fed and clothed and sent inland and to the south 35,000 persons. This organization will henceforth also give assistance to civil prisoners and to soldiers mustered out of service in the devastated regions.

Nurse Receives Decoration of Legion of Honor

Mme. Marguerite Dislère, a nurse serving with the ambulance 9/10, has been made a chevalier of the Legion of Honor, with the following citation: "A nurse of the first order, of very high moral quality, accomplished in her profession and most zealous in her work. She rendered priceless service during the campaign in Morocco and during the earthquake catastrophe at Messina. At the front since Aug. 1, 1914, at Verdun, where she contracted typhoid caring for the sick, and where she was exposed to several bombardments; at Vadelincourt, at Ressons-sur-Matz; at Noyon, in the Somme, the Oise and the Vosges districts, she always gave proof, even under enemy fire, of the greatest courage and utmost contempt for danger, devoting herself with indefatigable energy to extending motherly care to the sick and wounded, furnishing an example of limitless devotion. Once wounded. Already cited twice in army orders."

Bread Ration for Pregnant Women

M. Raoul Méquillet, deputy, asked the minister of agriculture and food commissioner what the bread ration of pregnant and nursing women is at present. He received the following reply: Pregnant women, who are employed, are classed in the category T of the individual food card (daily bread ration of 500 gm.), as soon as they register themselves with the mayor and during a period of six months on condition that this registration is accompanied by a medical certificate setting forth their condition. Following the confinement, the classification in Class T will be continued for fifteen months, providing that the mother nurses the infant herself. Besides this, a daily bread ration of 100 gm. is allowed for the infant from the date of birth.

Personal

At the last meeting of the Académie de médecine, Prof. A. Laveran, a member of the academy since 1893, was elected vice president for 1919, automatically becoming president in 1920.

Deaths

Dr. Tanton, consulting surgeon of the Fourth Army, formerly a member of the faculty of l'Ecole d'application de médecine et de pharmacie militaires du Val-de-Grâce, died in his hospital at Mont-Frenet.——Dr. Vigouroux, physician in chief of the hospitals for the insane in the department of the Seine.

Marriages

Jay Melancthon Kilborne, Capt., M. C., U. S. Army, to Miss Lavisa Pinkley, both of Sioux City, Iowa, at Des Moines, Iowa, January 18.

Claude Allen Thompson, Major, M. C., U. S. Army, to Miss Alva Coulter, January 16, both of Muskogee, Okla.

George Asbury Conrey, Lieut., M. C., U. S. Army, to Miss Cornelia M. Keating, both of Chicago, January 18.

Addison Eugene Elliott, El Centro, Calif., to Dr. Frances Pullen Chapman of Oak Park, Ill., January 11.

Harry J. Arnold to Miss Martha Bean, both of Columbus, Neb., January 11.

Deaths

Thomas Francis Harrington ⊕ Boston; Harvard Medical School, 1888; aged 52; a specialist on internal medicine; a member of the American Association for the Study and Prevention of Tuberculosis, and American Association of Life Insurance Examiners; formerly visiting and later consulting physician to St. John's Hospital, Lowell, Mass.; deputy commissioner of the state board of labor and industry since 1915; for three years chairman of the board of health of Lowell; director of the school of hygiene in the Boston public schools from 1907 to 1915; instructor in the school for teachers at Harvard and the Massachusetts Institute of Technology; physician in chief of St. Elizabeth's Hospital; originator of "health days" and author of the History of Harvard Medical School; an internist of high repute; lieutenant-colonel, M. C., Mass. V. M.; died at his home in Boston, January 19, from ptomain poisoning.

John Henry Lowman ⊕ Cleveland; College of Physicians and Surgeons in the City of New York, 1877; aged 68; professor of clinical medicine and medical ethics in Western Reserve University, Cleveland; physician to Lakeside Hospital; consulting physician to Charity, City, Lutheran, and St. John's hospitals; director of Municipal Tuberculosis Dispensary; a member of the American Laryngological Association; who headed the first American Red Cross tuberculosis mission to Italy; died in New York City, January 23.

Urban S. Bird ⊕ **Lieut., M. C., U. S. Army,** Tampa, Fla.; Tulane University, New Orleans, 1895; aged 52; a specialist on diseases of the eye, ear, nose and throat; a member of the American Laryngological, Rhinological and Otological Society; for several terms city physician of Tampa; surgeon of U. S. Volunteers during the war with Spain, with service in Cuba; who was honorably discharged from the Army, December 5; died, about January 11.

Newcomb S. Smith, Rapid City, S. D.; College of Physicians and Surgeons, Keokuk, Iowa, 1864; aged 79; hospital steward on the Thirty-Second (Iowa) Volunteer Infantry, afterward assistant surgeon of the Thirty-Fifth (Iowa) Volunteer Infantry in the Civil War, and later a surgeon in the regular establishment with station at Fort Randall, Okla.; died in the Soldier's Home, Marshalltown, Iowa, January 9, from carcinoma of the throat.

William Bird Van Lennep, Philadelphia; Hahnemann Medical College, Philadelphia, 1880; aged 65; professor of surgery in his alma mater since 1884, and for several years dean of the faculty; senior surgeon and consulting surgeon to several hospitals in Philadelphia and Camden, N. J.; chief surgeon of the Hahnemann Hospital; a specialist in abdominal surgery; died at his home, January 9, from heart disease.

Thomas Kelley ⊕ New York City and Deal, N. J.; New York University, New York City, 1884; aged 55; a member of the New York Academy of Medicine; attending physician to St. Vincent's and St. Laurence hospitals, and the Catholic Institute for the Blind, and Seton Hospital, Spuyten Duyvil; died suddenly from cerebral hemorrhage in his automobile while making a professional call, January 17.

Gilbert Birdsall, North Brookfield, N. Y.; University of Buffalo, N. Y., 1863; aged 89; at one time a member of the Medical Society of the State of New York; hospital steward during the Civil War; for four years postmaster of Oneida, for sixteen years justice of the peace, and for fifteen years president of the board of education; died at his home, January 16, from acute indigestion.

Otto Louis Winter ⊕ **Lieut., M. C., U. S. Army,** St. Paul; University of Minnesota, Minneapolis, 1915; aged 30; a specialist in orthopedic surgery; whose last station was chief of the orthopedic service in the reconstruction hospital, Fort Snelling, Minn.; died at the home of his father in River Falls, Wis., January 2, from pneumonia following influenza.

Henry Virgil Bogue ⊕ **Asst. Surg. (j. g.), U. S. N. R. F.,** Los Angeles; Baltimore Medical College, 1909; aged 34; a specialist on diseases of the eye, ear, nose and throat; staff surgeon to the Los Angeles County Hospital; on duty at the Mare Island Naval Hospital, Vallejo, Calif.; died in that institution, January 9, from pneumonia following influenza.

William Sutherland Connery ⊕ Saginaw, Mich.; University of Michigan, Ann Arbor, 1889; aged 50; formerly president of the Saginaw County Medical Society; surgeon to the Saginaw and St. Mary's hospitals; formerly coroner of Saginaw County; a veteran of the war with Spain; died at his home, December 23, from cirrhosis of the liver.

Nathaniel Clark Morse ⊕ Eldora, Iowa; Cincinnati College of Medicine and Surgery, 1877; aged 62; district surgeon of the Chicago and Northwestern Railway; surgeon in chief of the Emergency Hospital; formerly president of the State Society of Railway Surgeons, and vice president of the Pan-American Medical Congress; a member of the Western Surgical Association; died at his home, January 18, from heart disease.

Bertram Hughey Landes, Logansport, Ind.; Indiana University, Bloomington and Indianapolis, 1911; aged 32; a member of the Indiana State Medical Association; a member of the staff of the Longcliff Asylum, Logansport; died in that institution, January 13, from pneumonia following influenza.

Allison R. Stealy ⊕ Charlotte, Mich.; Rush Medical College, 1886; aged 62; formerly president, secretary and treasurer of the Eaton County (Mich.) Medical Society; for several years health officer of Charlotte, and a member of the local board of education; died at his home, January 9.

Bradford Allen Booth ⊕ Pittsburgh; University of Pittsburgh, 1901; aged 40; chief medical inspector and diagnostician of the department of health of Pittsburgh, and visiting physician to the Municipal Hospital for Contagious Disease; died at his home, January 13, from heart disease.

Frank Walton Mitchell, Bakersfield, Calif.; College of Physicians and Surgeons in the City of New York, 1880; a member of the Medical Society of the State of California; died at his home, January 12, from cerebral hemorrhage.

William Hayden Campbell, Santa Monica, Calif.; Gross Medical College, Denver, 1890; aged 70; at one time a member of the Medical Society of the State of California, and Montana State Medical Association; died, January 8, at his home, near Los Angeles.

Samuel Solovei ⊕ **Lieut., M. C., U. S. Army,** Brooklyn; College of Physicians and Surgeons in the City of New York, 1917; aged 25; while on his second trip to France was taken ill on the steamer and died at a base hospital in Brest, October 15, from pneumonia.

Lewis Wesley Kitchens ⊕ **Lieut., M. C., U. S. Army,** Senatobia, Miss.; University of Tennessee, Nashville, 1914; aged 31; on duty with the American Expeditionary Forces in France; died in Calais, France, October 30, from pneumonia following influenza.

Horace Cortelyou Cory ⊕ Newark, N. J.; College of Physicians and Surgeons in the City of New York, 1898; aged 52; a specialist in surgery; and a member of the staff of St. Michael's Hospital, Newark; died at Saratoga Springs, N. Y., January 15.

Nathaniel H. Saxman, Philadelphia; University of Pennsylvania, Philadelphia, 1890; aged 53; formerly a member of the Medical Society of the State of Pennsylvania; died in the Jewish Hospital, Philadelphia, January 8.

William Francis Rafferty ⊕ **Lieut., M. C., U. S. Army,** Rensselear, N. Y.; Albany (N. Y.) Medical College, 1911; aged 31; for two terms coroner of Rensselaer County; died suddenly from heart disease while making a professional call, January 15.

Abraham Sachs, San Antonio, Texas; Miami Medical College, Cincinnati, 1900; aged 46; a member of the State Medical Association of Texas; and a specialist on diseases of the eye, ear, nose and throat; died at his home, January 19.

Carl Adolph Breitling ⊕ **Lieut., M. C., U. S. Army,** Brooklyn; Northwestern University Medical School, 1913; aged 32; on duty at Camp Greenleaf, Fort Oglethorpe, Ga.; died at Fort Oglethorpe, November 5, from bronchopneumonia.

Allen Lewis Borden, Gowanda, N. Y.; University of Michigan, Ann Arbor, 1896; aged 46; a member of the Buffalo Academy of Medicine, and health officer of Gowanda and Cattaraugus County; died at his home, January 10.

John E. Wade, Brooklyn; New York University, New York City, 1871; aged 71; a member of the Medical Society of the State of New York; died at his home, January 10.

James Harvey Cole ⊕ Council Bluffs, Iowa; University of Illinois, Chicago, 1892; aged 48; vice president of the Harle-Hass Drug Company, Council Bluffs; who was a patient in a private hospital in Des Moines, Iowa; died there, December 10, from a nervous breakdown.

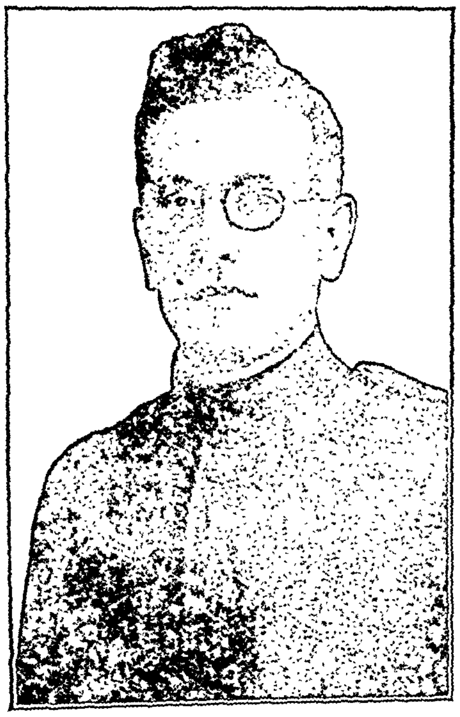
Charles Anthony Saxon, Clinton, S. C.; Jefferson Medical College, 1856; aged over 80; formerly a member of the South Carolina Medical Association; died at the home of his daughter-in-law in Laurens, S. C., January 5.

Demsey Franklin Smith, Whitesburg, Ky.; Hospital College of Medicine, Louisville, Ky., 1907; aged 42; a member of the Kentucky State Medical Association; died at his home, October 21, from pneumonia following influenza.

Glennie H. Rutledge, Afton, Okla.; American Medical College, St. Louis, 1907; aged 36; a member of the Oklahoma State Medical Association; died at his home, November 2, from pneumonia following influenza.

N. E. Palmer, Dundee, Minn. (license, Iowa, years of practice, 1886); aged 84; for several years a druggist at Kirkman and Botna, Iowa; died at the home of his son in Dundee, December 9.

Sidney Bennett Rolison, Hesperia, Mich.; University of Michigan, Ann Arbor, 1881; aged 70; a member of the Michigan State Medical Society; died at his home, January 11.



Died in the Service
IN FRANCE
Lieut. Sidney C. Vermilyea, M.C.
U S. Army, 1887-1918
(See The Journal, Jan. 18, p. 211)

Samuel S. Spicer, Grinnell, Iowa; Washington University, St. Louis, 1873; aged 66; at one time a member of the Iowa State Medical Society; died at his home, January 11, from heart disease.

John G. Halloway, Ottumwa, Iowa (license, Iowa, years of practice, 1887); aged 79; a veteran of the Civil War; also a clergyman; died at his home, January 4, from cerebral hemorrhage.

James F. White, Richview, Ill.; Medical College of Ohio, Cincinnati, 1874; aged 73; a member of the Illinois State Medical Society; died at his home, October 20, from influenza.

Edward T. Gauvreau, Superior, Wis. (license, Wisconsin, 1899); aged 75; a practitioner for forty-six years; for several years health officer of Superior; died at his home, January 13.

Phillipe Sharples Hall, Philadelphia; Hahnemann Medical College, Philadelphia, 1891; aged 52; formerly professor of pathology in his alma mater; died at his home, January 16.

Jacob Loy, Cedar Rapids, Iowa; Eclectic Medical Institute, Cincinnati, 1853; aged 91; a veteran of the Civil War; died at the home of his daughter in Cedar Rapids, January 9.

John C. O'Brien ⊕ Elmira, N. Y.; Western Reserve University, Cleveland, 1888; aged 68; a member of the Elmira Academy of Medicine; died at his home, about January 9.

John D. Masengill, Blountville, Tenn.; College of Physicians and Surgeons, Baltimore, 1874; aged 74; at one time a member of the Tennessee State Medical Association; a Confederate veteran; died at his home, January 9.

John Henry Reesor, Louisville, formerly Stithton, Ky.; Louisville (Ky.) Medical College, 1885; aged 60; a member of the Kentucky State Medical Association; died at his home, January 1, from pulmonary abscess.

William Patrick Wilson, Hartford, Conn.; College of Physicians and Surgeons, Baltimore, 1890; aged 61; a member of the Connecticut State Medical Society; died at his home, December 19, from heart disease.

William Henry Sheldon, Middlebury, Vt.; Bellevue Hospital Medical College, 1880; aged 63; also a druggist; died at his home, January 12, from disease of the throat.

William P. C. Schunzel, Chicago; Hahnemann Medical College, Chicago, 1917; aged 33; died at his home, January 20, from a ruptured aneurysm of the aorta.

Martin Vaughan, Hammond, Ind. (license, Indiana, 1898); aged 82; died in Augustana Hospital, Chicago, January 10, from uremia, after a surgical operation.

The Propaganda for Reform

In This Department Appear Reports of the Council on Pharmacy and Chemistry and of the Association Laboratory, Together with Other Matter Tending to Aid Intelligent Prescribing and to Oppose Medical Fraud on the Public and on the Profession

B. IODINE AND B. OLEUM IODINE

Report of the Council on Pharmacy and Chemistry

The Council has authorized publication of the following report on "B. Iodine" and "B. Oleum Iodine" together with the reply submitted by the manufacturer and a discussion thereon by the referee in charge of the preparations.

W. A. Puckner, Secretary.

Specimens of B. Iodine and B. Oleum Iodine (B. Iodine Chemical Company) and an advertising pamphlet were sent to the Council by John Bohlander, A.M., M.D., with the declaration:

> "Well knowing the value of Iodin in surgical operations and dressings, prompted me for the benefit of my fellow physicians as well as myself, and for Humanity's sake, to make Iodin my master-piece in chemistry.
>
> "After several years of diligent work in my private laboratory I succeeded in discovering a new product of Iodin—Nitrogen, hydrate of Iodin."

While "B. Iodine" is said to be nitrogen hydrate of iodin and "B. Oleum Iodine" a 5 per cent. solution thereof, the examination made by Prof. A. H. Clark of the University of Illinois, School of Pharmacy (working in the A. M. A. Chemical Laboratory), indicates that the first is a simple mixture of iodin and ammonium iodid, and the second a solution of iodin in liquid petrolatum. The Council adopted the report of the A. M. A. Chemical Laboratory (which appears below) and declared B. Iodine and B. Oleum Iodine inadmissible to New and Nonofficial Remedies because:

1. The composition is incorrectly declared. B. Iodine is not a newly discovered iodin compound, "Nitrogen Hydrate of Iodine," but a mixture of iodin and ammonium iodid. B. Oleum Iodine is not a 5 per cent. solution of B. Iodine as suggested by the statement on the label and in the advertising, but a solution of iodin in liquid petrolatum containing about 0.85 per cent. of iodin.

2. Since B. Iodine is a mixture of iodin and ammonium iodid, its solution in water will have the properties of other solutions of iodin made by the aid of iodid, such as a dilution of tincture of iodin or of compound solution of iodin (Lugol's solution). Hence, the therapeutic claim that B. Iodine "being of a colloidial nature has the advantage of being more readily absorbed and taken up by all cellular structure, thus getting a perfect cellular medication of Iodine," is unwarranted.

3. The names "B. Iodine" and "B. Oleum Iodine" are not descriptive of the pharmaceutical mixtures to which they are applied.

4. B. Iodine and B. Oleum Iodine are unessential modifications of established articles. B. Iodine has no advantage over tincture of iodin or compound solution of iodin. (As more convenient of transportation, the Medical Department of the U. S. Army supplies its field hospitals with a mixture of iodin and iodid ready for solution in water, either in tablet form or in powdered form in tubes.) Solutions of iodin in liquid petrolatum may be readily prepared (Reports Council Pharm. and Chem., 1917, p. 88).

[Contribution from the A. M. A. Chemical Laboratory]

B. IODINE PRODUCTS

A. H. Clark, Ph.G., B.S.

"B. Iodine" products are marketed by the B. Iodine Chemical Company, Cincinnati, Ohio; John Bohlander, A. M., M.D., is said to be the discoverer. They consist of "B. Iodine," "B. Oleum Iodine," and "B. Aqua Iodine." B. Iodine and B. Oleum Iodine were submitted to the Council.

In a circular submitted by the B. Iodine Chemical Company, B. Iodine is said to be "Nitrogen Hydrate of Iodin." It is claimed that "coming in contact with water, H_2O, a chemical change takes place forming Hydro Oxid of Iodin, the Nitrogen of the Nitrogen Hydrate of Iodin escaping, the balance taking up one of oxygen of the water. Its companion, the H_2, escaping at the same time with the Nitrogen then combining with the remainder of the water to form the solution of Hydrogen Oxid of Iodin; so you can readily see that you really have a pure water of Iodin, nothing but the H, the O and the I."

B. IODINE

According to the circular, B. Iodine is soluble in alcohol, chloroform, and ether. Also it:

> "Has odor, taste, melting and boiling point, same as regular Iodin, has a great affinity for water and will respond to all the tests of Iodin. Appears in a Bluish Black Granulated mass or powder. When heated in vaporating dish will throw off large purple volumes of Iodin leaving a slight white crystaline precipitate, which on continuous heating will entirely disappear. With careful manipulation you can get prismatic needle point like crystals, looking like spores of glass, these dissolving in water will yield pure Iodin coloring the water Iodin.
>
> "Pharmacologic, Therapeutical and Physiological Action: Same as Iodin, being of a colloidal nature has the advantage of being more readily absorbed and taken up by all cellular structure, thus getting a perfect cellular medication of Iodin."

A sample of B. Iodine, marked "Nitrogen Hydrate of Iodin" was submitted by the manufacturers and this sample was examined.

B. Iodine was found to be a granular powder, almost black with a purple cast. It has an odor of iodin and dissolves in water readily. It is also quite soluble in alcohol, but not entirely soluble in chloroform and ether. Ether quickly dissolves iodin from B. Iodine leaving a residue of a white granular substance. Chloroform acts the same as ether except that the iodin is dissolved out with some difficulty. On heating B. Iodine, vapors of iodin escape. If the heating is done on a water bath, a residue of a white granular substance, subsequently identified as ammonium iodid, remains. If heated in a bunsen flame, no residue remains. These tests all indicate that iodin is held in the form of a simple mixture.

Ammonia: B. Iodine when mixed with an excess of sodium hydroxid and warmed, evolves ammonia.

Iodine: 0.1567 gm. B. Iodine dissolved in water required 5.88 c.c. tenth-normal sodium thiosulphate solution indicating 48.28 per cent. iodin. 0.3721 gm. B. Iodine required 14.18 c.c. tenth-normal sodium thiosulphate solution indicating 48.37 per cent. iodin. The average is 48.33 per cent. iodin.

Ammonium Iodide: 0.3453 gm. of the residue after heating B. Iodine on a water bath until all iodin had volatilized was dissolved in water, acidulated with phosphoric acid, and hydrogen dioxid solution added. The liberated iodin was extracted with chloroform and titrated with tenth-normal sodium thiosulphate. 23.78 c.c. were required indicating 0.3447 gm., or 99.83 per cent., ammonium iodid.

A mixture of 5 gm. iodin and 5 gm. ammonium iodid has the properties of B. Iodine mentioned above.

The conclusion is that B. Iodine is essentially a mixture of iodin and ammonium iodid in equal parts, the two substances being finely powdered and intimately mixed.

B. OLEUM IODINE

The following regarding B. Oleum Iodine is quoted from the circular submitted:

> "B. OLEUM IODINE: Iodine soluble in mineral oil 5 and 10% for Nasel, Pharyngeal, Laryngeal, Bronchial, Rectal, etc., and all meucoid affections and abnormal conditions of the mucous membrane."

A sample of B. Oleum Iodine was submitted by the manufacturer and examined. The label on the bottle states that it is 5 per cent. B. Oleum Iodine in mineral oil. This sample has the characteristics of a solution of iodin in liquid petrolatum. It is oily and has the characteristic violet color.

Ammonia: B. Oleum Iodine, since it is presumed to be a solution of B. Iodine, was examined for ammonium compounds. A small quantity was mixed with an equal volume of strong sodium hydroxid solution and heated. No ammonia was evolved. A few crystals of ammonium chlorid were added to a little of B. Oleum Iodine and treated as above. Ammonia was readily detected.

Iodine: 5.255 gm. B. Oleum Iodine was dissolved in chloroform and placed in a separator. A solution of potassium iodid was added and the iodin titrated with tenth-normal sodium thiosulphate solution. It required 3.5 c.c. indicating 0.85 per cent. iodin.

The conclusion is that B. Oleum Iodine is a simple solution of iodin in liquid petrolatum to the extent of 0.85 per cent.

and not 5 per cent. as claimed. Furthermore, it is not a solution of B. Iodine since no ammonium compound is present.

The preceding report was sent to the B. Iodine Chemical Company. The following reply was received:

> Your letter of the 21st inst., received and contents noted and cannot quite agree with your report.
>
> Reasons why: NH_4I, a Nitro Hydrate Iodide; NH_4I_2, a Nitro Hydrate Iodate; and $NH_4I_2I_2$, Per Iodide, a molecular compound, which I claim, they all being of a NH group, so what can be the objection of Nitrogen Hydrate of Iodine? Of course when your chemist, with the aid of heat, drove off all the Iodine, he naturally brought it back to a NH_4I. There's where he gets the A.M. I claim a molecular compound.
>
> The Oil of Iodine I sent you by mistake was a 1 per cent. and not a 5 per cent. as marked. I claim it is made from the resublimed Iodine in mineral oil and not the B. Iodine. I claim a 5 per cent. has heretofore never been accomplished, so I therefore can claim something new.
>
> Tr. Iodine contains Alcohol and Potash as a base, the alcohol a dehydrater and Potash an escharotic, and all other soluble Iodines like the tincture have a metallic base. Mine has not. My iodine is compatable almost with all the salts, alkaloids, tannates, and even the metals. You can't say that for the tincture or the others. Now why should mine not be superior to others?
>
> Preparations as yet are not on the market and a few pamphlets were printed to meet with the requirements of your rulings and approval and shall be corrected if we only can agree on a proper name as you may suggest.
>
> Yours very truly,
>
> The B. Iodine Chemical Co.
> By John Bohlander, A.M., M.D.
>
> P. S. We are sending you under separate cover another sample of the Oil of Iodine which is a 5 per cent. solution, and allowing for deterioration will test at least four per cent.

The referee in charge of the preparations submitted the above letter to the Council with the following comments:

The principal statements in the letter are essentially erroneous or misleading: Mixtures or double salts of ammonium iodid and iodin were not discovered by Dr. Bohlander, and are nothing new. Watery solutions of iodin by means of an iodid have long been known and used in the form of Lugol's solution.

There is no evidence that ammonium iodid is less irritating than potassium iodid. On the contrary, ammonium salts are generally more irritating than the corresponding potassium salts. B. Iodine is not compatible with alkaloids, but behaves essentially like Lugol's solution. The A. M. A. Chemical Laboratory reports that the new sample of B. Oleum Iodine contains only 1.2 per cent. of free iodin, instead of the claimed amount. It is therefore somewhat weaker than the iodin petrolatum prepared by the A. M. A. Chemical Laboratory (*Reports Council Pharm. and Chem.*, 1917, p. 88).

However good Dr. Bohlander's intentions may be, the statements that he makes about his products are misleading or erroneous, and the products are ineligible for N. N. R.

Correspondence

"A REGISTRATION FEE FOR PHYSICIANS"

To the Editor:—Dr. Blair Kelly's protest (The Journal, Jan. 25, 1918, p. 298) against the proposition of an annual registration fee for physicians ascribes to me an attitude which is far removed from my thought. One of the responsibilities placed on the director of registration and education in Illinois is the enforcement of the medical practice act. This act represents the cumulative effort of years of work by members of the medical profession. It is an excellent law and is much in advance of any previous similar statute of Illinois. The civil administrative code, which established the department of registration and education, provides that the department of registration and education, provides that in all professional matters relating to medicine the officers of the department shall be advised by a committee of five physicians, men who are licensed to practice medicine and surgery in all their branches. Under the law no one can be admitted to practice medicine or debarred from it without the recommendation in writing by these guardians of the interests of the medical profession. This legal requirement is an absolute obstacle to any undue assumption of authority by the director. It was while working in hearty cooperation with this committee in an attempt to correct some recognized abuses that the desirability of an annual registration fee for physicians became apparent.

It ought to be clear that it is extremely difficult to administer a law relating to a certain profession without having any means at all of knowing what individuals are entitled to the privileges of that profession and what ones are not. So far as the department of registration and education is concerned, it has no motive and no desire as to medicine except to aid in the advancement of the interests of the profession in Illinois. It seeks only to build more firmly on the substantial foundations which have been laid through many years of efficient endeavor by those local, county, state and national organizations in medicine which have been working steadily toward the improvement of professional conditions.

So far as Dr. Kelly's suggestion of a possible financial motive in urging an annual registration fee is concerned, perhaps it is only necessary for me to say that under the law all funds received by the department must be paid into the state treasury every ten days, that no money is paid out by the treasurer except on a proper voucher approved by the director of the department, the director of finance and the governor, and that no positions of any kind are created except through the Civil Service organization. With these safeguards, no one should fear improper use of funds by a director.

Francis W. Shepardson, Springfield, Ill.
Director of Registration and Education.

ANNUAL REGISTRATION OF PHYSICIANS

To the Editor:—An editorial comment entitled "Annual Registration of Physicians, and a Danger" appeared in The Journal, Jan. 11, 1918, p. 122. If this matter could be brought to vote among the thousands of reputable physicians in our country, the law would never pass. It is a matter of common knowledge that sons of physicians only seldom study medicine, but are more apt to go into business or law. It is not unreasonable to believe that one cause of this is that fathers do not wish to subject their sons to certain needless and often petty restrictions imposed on members of the profession. It is also well recognized that the tendency of the times is for young men to enter commercial and mechanical fields rather than the study of medicine. True, certain educators may not deplore this fact, feeling that the profession has been overcrowded. There is no danger that it will be overcrowded in the future. The wisdom may be questioned of making laws which will bear on something like 145,000 earnest, conscientious members of a great profession, in order to locate a few rascals. It is well known that our profession does not command the respect of the people in our own country as it does in some other countries. It is not improbable that laws such as the one in question arouse doubt and suspicion in the minds of the people toward members of the profession.

Francis H. MacCarthy, M.D., Boston.

"THE TREATMENT OF AMEBIC DYSENTERY WITH IPECAC BY RECTUM"

To the Editor:—The Journal, Sept. 28, 1918, and more recently, Jan. 18, 1919, published the results and experiences of Dr. G. B. Lawson and Dr. J. Cecikas on the treatment of amebic dysentery with ipecac by rectum. If you will turn to the classical memoir on dysentery and its treatment by Dr. Woodward, in the "Medical History of the War of the Rebellion," Part II, pp. 832 et al., you will find an interesting and valuable contribution on the subject. Doubtless the fact that ipecacuanha or emetin so often fell into disrepute through reports by earlier authorities was due to our ignorance of the part played by the endameba in the production of amebic dysentery. Fortunately now our cases may be selected. Recently I had occasion to use myristica (nutmeg) in the treatment of amebic dysentery, which justifies a trial when emetin has failed, or in those asthenic cases which contraindicate its use. The report covering this investigation is in the hands of the publishers with the permission of the Surgeon-General of the Army. To those who are specially interested in the subject of dysentery, permit me to recommend reference to Woodward's memoir, a veritable mine of information. It will add corroboration to the "saw" of old, "There is nothing new under the sun." From observations in a number of our camps during the present war, I am of the opinion that amebic dysentery will be more common in our clinics than it has been in former years, not only among those who formed the American Expeditionary Forces, but also among those who got no farther than our Southern camps.

JOSEPH LEIDY, M.D., Philadelphia.

ANESTHETISTS IN HOSPITALS

To the Editor:—It has been brought to my attention, from various sources, that certain hospitals and surgeons employing nurses as anesthetists are paying these nurses on an average of $3 an anesthetic, while collecting from $10 to $15 from the patients for the anesthetic service rendered. In this connection I should appreciate receiving verified information regarding individual instances of this practice, for submission to those in a position to deal with the matter.

Incidentally, this practice has also involved the disbarment of licensed and qualified physicians from administering anesthetics in certain hospitals, the superintendents and surgeons of which are exploiting nurses as anesthetists. I should also like to have the detailed facts of such disbarment from all legally qualified practitioners who have been thus made the victims of a peculiar form of boycott.

F. H. MCMECHAN, M.D., Avon Lake, Ohio.
Secretary, American and Interstate Associations of Anesthetists.

RESULTS OF GENERAL ORDER 73 ON DEMOBILIZATION

To the Editor:—As the American Medical Association proved of great benefit to the Surgeon-General in the matter of obtaining physicians for the Medical Reserve Corps, it is probable that an objection from you concerning some of the practices now in force in the discharging of officers would have more weight than if from us as individuals. I refer to the changing of the status of the reserve officers by G. O. 73, W. D. 1918, and the practice of letting men out of the service without previous notice.

Those of us who entered the service prior to August were members of the Reserve Corps, commissioned to serve five years, on active service during a national emergency. At the termination of the emergency, we were to be ordered to our homes and there placed on an inactive basis. This gave us pay during the period of travel, and also the travel allowance of 7 cents a mile. But by the provisions of G. O. 73, the old Reserve was abolished. I wrote to the Surgeon-General some weeks ago, and recently had a reply to my question, in which it was stated that the members of the old Reserve were discharged, and that we were now all members of the National Army. As such we would be discharged where we might be serving, and would draw 4 cents a mile from the place of discharge. At the medical officers' training camp we were given to understand that we could not be discharged except by the President, and yet here was a wholesale slaughtering of commissions without any of us being asked so much as by your leave, again commissioned on an entirely different status, and all in the twinkling of an eye. In my own case, this order represents a loss to me of over $150, as I am now something over 3,000 miles from my home, and the difference in mileage plus the five days' pay that I lose, since discharges take effect before leaving one's last station, not on arrival at home, will be fully that much.

Furthermore, men are being discharged from this station, and I am told by friends elsewhere that this is not peculiar to this post, on a few minutes' *notice*. *This* means a further loss in pay, as usually one cannot pick up and leave without some little time to clear from property, etc.

I have personally talked to about a hundred medical officers. Is it any wonder that I have not yet been able to find one that will stay in the Reserve?

LIEUT., M. R. C.

[COMMENT.—We believe that our correspondent is correct in his statement, and that under General Order 73, which combined all branches of the service, officers of the Reserve Corps have had all the privileges of their former status as reserve officers removed. The Judge Advocate General has held that it is not possible to restore automatically reserve officers to the status they held before the issuing of General Order 73.—ED.]

Queries and Minor Notes

ANONYMOUS COMMUNICATIONS and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted, on request.

CUMULATIVE ACTION OF STRYCHNIN—DISPENSING OF PHARMACOPEIAL TINCTURES AND FLUIDEXTRACTS

To the Editor:—1. Owing to the cumulative action of strychnin, would it be safe for a person of medium weight to take one-thirtieth grain four times a day for a period of one year? 2. I dispense small quantities of tinctures and fluidextracts which I keep in my office and carry in my bag. I am not bonded. Am I violating the law; if so, how should I proceed to comply with it? Please do not print my name.

C. S. R.

ANSWER.—1. Authorities do not all agree that strychnin has a cumulative action. Some state that large doses of strychnin may lead to toxic symptoms through cumulation. According to Hatcher and Wilbert, no danger of serious poisoning is to be feared when the daily dosage is limited to 0.01 gm. (one-sixth grain) and the administration of the drug stopped on the appearance of increased sensitivity of the reflexes. While it might be safe to give one-thirtieth grain of strychnin four times a day for a period of one year, there would seem to be no reason for continuing the administration of the drug over such a long period. It would be better, perhaps, to give one-twentieth grain three or four times a day for from ten days to two weeks and then to discontinue for a week or two before repeating.

2. Physicians who dispense small quantities of pharmacopeial tinctures and fluidextracts need not be bonded.

"THE SURGICAL TREATMENT OF EMPYEMA BY A CLOSED METHOD"

To the Editor:—In THE JOURNAL, Dec. 21, 1918, p. 2062, is an article on the treatment of empyema by a new method. I think it is an old operation, done in the eighties as the "Bülau operation," and spoken of in an article by Immermann in the *Deutsche medizinische Wochenschrift* of 1887. This statement is made for the purpose of correctness; hence I would thank you if you could verify it.

G. WILLIAM POEHL, M.D., St. Louis.

ANSWER.—The article to which our correspondent refers was by Immermann, in the *Deutsche medizinische Wochenschrift* **13**:169, 1887. Immermann's method, which is said to be a modification of one he saw used in Basle (the name of the operator is not mentioned) and, again, later in Hamburg by Curschmann, consists in emptying and continuous aspiration of the fluid from the chest abscess. The method is like that described in THE JOURNAL by Mozingo in the first step, the making of the puncture and the insertion of a drainage tube; after that the two differ. Immermann does not use an aspirating syringe, nor does he inject any fluid into the abscess cavity. He merely provides for continuous drainage into a bottle containing salicylic acid or thymol solution, but, like Mozingo, insists on having an air-tight drainage tube so that the expanding lung will gradually obliterate the abscess cavity, and hence prevent the formation of adhesions.

Mortality Due to Snakes and Animals in India.—Vice Consul Charles M. Haywood at Calcutta (*Commerce Reports*) says that snake bite caused the death of 23,918 persons in British India in 1917, an increase of nearly 300 over the previous year. The number of snakes destroyed increased from 65,765 in 1916 to 73,968 in 1917, for the killing of which bounties to the amount of $1,045 were paid. Wild animals killed 2,176 persons in 1917, 102 less than in 1916. Tigers were responsible for 1,009 deaths, leopards for 339, wolves and bears for 280 and elephants and hyenas for 89. Of the 149 deaths caused by other animals, 89 were caused by pigs and 199 by crocodiles and alligators. During the year 19,476 wild animals were destroyed, of which 1,295 were tigers, 6,037 leopards, 2,784 bears and 2,147 wolves.

Medical Education and State Boards of Registration

COMING EXAMINATIONS

Alaska: Juneau, March 4. Sec., Dr. L. P. Dawes, Juneau.

California: Los Angeles, March 17-20. Sec., Dr. C. B. Pinkham, State Capitol, Sacramento.

Connecticut: New Haven, March 11-12. Sec. Reg. Bd., Dr. Chas. A. Tuttle, 196 York St., New Haven; Sec. Eclectic Bd., Dr. J. E. Hair, 730 State St., Bridgeport, and Sec. Homeo. Bd., Dr. E. C. M. Hall, 82 Grand Ave., New Haven

Illinois: Chicago, March 3-5. Mr. F. C. Dodds, Supt. of Registration, Springfield.

Indiana: Indianapolis, Feb. 26-28. Sec., Dr. W. T. Gott, 84 State Capitol Bldg., Indianapolis.

Kansas: Topeka, Feb. 11. Sec., Dr. H. A. Dykes, Lebanon.

Massachusetts: Boston, March 11-13. Sec., Dr. W. P. Bowers, Rm. 501, No. 1 Beacon St., Boston.

Nebraska: Lincoln, Feb. 12. Sec., Dr. H. J. Lehnhoff, 514 First Natl. Bank Bldg., Lincoln.

New Hampshire: Concord, March 13-14. Sec., Dr. Charles Duncan, Concord.

Vermont: Burlington, Feb. 11. Sec., Dr. W. Scott Nay, Underhill.

Wyoming: Moorcroft, Feb. 12-14. Sec., Dr. H. E. McCollum, Laramie.

Wyoming October Examination

Dr. H. E. McCollum, secretary of the Wyoming State Board of Medical Examiners, reports the written examination held at Laramie, Oct. 10-12, 1918. The examination covered 10 subjects and included 100 questions. An average of 75 per cent. was required to pass. Ten candidates were examined, including 2 osteopaths, all of whom passed. The following colleges were represented:

College	Year Grad.	Per Cent.
PASSED		
Chicago Hospital College of Medicine	(1918)	80.6, 80.8, 83.4, 88.6, 89.9
Loyola University	(1917)	82.9
National University of Arts and Sciences	(1915)	85
St. Louis College of Phys. and Surg.	(1917)	90.7

Nevada November Examination

Dr. S. L. Lee, secretary of the Nevada State Board of Medical Examiners, reports the written examination held at Carson City, Nov. 4-6, 1918. The examination covered 13 subjects and included 100 questions. An average of 75 per cent. was required to pass. Of the 5 candidates examined, 4 passed and 1 failed. Six candidates were licensed through reciprocity. *The following colleges were represented:*

College	Year Grad.	Per Cent.
PASSED		
College of Physicians and Surgeons, Los Angeles	(1916)	93.3
Hahnemann Medical College of the Pacific	(1918)	86, 89.8
University of Oregon	(1906)	94.4
FAILED		
University of Arkansas	(1914)	56.7

College	Year Grad.	Reciprocity with
LICENSED THROUGH RECIPROCITY		
Hahnemann Medical College and Hospital of Chicago	(1891)	Nebraska
Rush Medical College	(1875)	Illinois
State University of Iowa College of H. Med.	(1903)	Iowa
Albany Medical College	(1909)	Illinois
Bellevue Hospital Medical College	(1883)	Missouri
Medical College of Ohio	(1883)	Colorado

Massachusetts November Examination

Dr. Walter P. Bowers, secretary of the Massachusetts Board of Registration in Medicine, reports the oral, practical and written examination held at Boston, Nov. 13-15, 1918. The examination covered 13 subjects and included 70 questions. An average of 75 per cent. was required to pass. Of the 32 candidates examined, 22, including 3 osteopaths, passed, and 10, including 3 osteopaths, failed. The following colleges were represented:

College	Year Grad.	Per Cent.
PASSED		
College of Physicians and Surgeons, Los Angeles	(1917)	82.6
University of Colorado	(1911)	78.3
American Medical Missionary College	(1909)	75.6
Chicago Hospital College of Medicine	(1918)	75.4, 81.4
Hahnemann Med. Coll. and Hosp. of Chicago	(1918)	84.6
Medical School of Maine	(1876)	75.7
Baltimore Medical College	(1903)	75
Johns Hopkins University	(1918)	80.8
Boston University	(1882) 75.7; (1918)	78.5, 79.3
Tufts College Medical School	(1918)	78.5, 82
Syracuse University	(1918)	87.4
Jefferson Medical College	(1894)	75
Temple University	(1918)	77.7
University of Pennsylvania	(1918)	82.2
Woman's Med. Coll. of Penna.	(1906)	75
FAILED		
Chicago Hospital College of Medicine	(1918)	72.5
Baltimore Medical College	(1905)	69.7
College of Physicians and Surgeons, Boston	(1915)	68.2, 71.7
Middlesex College of Medicine and Surgery	(1918)	67.6, 70.3
Laval University	(1917)	71.8

Dr. Bowers also reports that 6 candidates were licensed at the special examinations given for emergency service. The following colleges were represented:

College	Year Grad.	Per Cent.
PASSED		
Georgetown University	(1889)	80
State University of Iowa College of Homeo. Med.	(1918)	79.5
Baltimore Medical College	(1897)	80.4
Boston University	(1918)	81
Harvard University	(1918)	82.7
Tufts College Medical School	(1918)	77.3

Delaware December Examination

Dr. H. W. Briggs, secretary of the Medical Council of Delaware, reports the practical and written examination held at Wilmington, Dec. 10-12, 1918. The examination covered 10 subjects and included 100 questions. An average of 75 per cent. was required to pass. Three candidates were examined, all of whom passed. Eight candidates were licensed through reciprocity. The following colleges were represented:

College	Year Grad.	Per Cent.
PASSED		
New York Homeo. Med. Coll. and Flower Hosp.	(1916)	90
Jefferson Medical College	(1918)	83.7
Temple University	(1918)	79.1

College	Year Grad.	Reciprocity with
LICENSED THROUGH RECIPROCITY		
Maryland Medical College	(1909) Maine; (1913)	Penna.
Southern Homeopathic Medical College	(1902)	Maryland
Jefferson Medical College	(1892) (1909) Penna; (1915)	Virginia
University of Pennsylvania	(1910)	Penna.
Woman's Medical College of Pennsylvania	(1916)	New York

Rhode Island January Examination

Dr. B. U. Richards, secretary of the Rhode Island State Board of Health, reports the oral, practical and written examination held at Providence, Jan. 2-3, 1919. The examination covered 7 subjects and included 70 questions. An average of 80 per cent. was required to pass. Of the 6 candidates examined, 5 passed and 1 failed. The following colleges were represented:

College	Year Grad.	Per Cent.
PASSED		
Harvard University	(1917)	90.3, 91
Tufts College Medical School	(1917)	88.9
Hahnemann Med. Coll. of Philadelphia	(1881)	80
University of St. Joseph, Beirut	(1894)	81.2
FAILED		
College of Physicians and Surgeons, Boston	(1910)	74

New York Meeting

Mr. George M. Wiley, director, Examinations and Inspections Division, reports that 17 candidates were licensed by indorsement of credentials from April 15 to Dec. 10, 1918. Thirteen candidates were granted reregistration certificates. The following colleges were represented:

College	Year Grad.	Endorsement with
LICENSED BY INDORSEMENT		
Chicago Homeopathic Medical College	(1885)	Indiana
Baltimore Medical College	(1895)	Delaware
University Medical College of K. C.	(1904)	Indiana
Albany Medical College	(1914, 2)	New Jersey
Columbia University	(1916)	New Jersey
Long Island College Hospital	(1895)	New Jersey
New York Homeo. Med. Coll. and Flower Hosp.	(1915)	Delaware
	(1916)	New Jersey
Eclectic Medical College	(1916)	Ohio
Western Reserve University	(1915)	Ohio
Jefferson Medical College	(1914)	Delaware
Medico-Chirurgical College of Philadelphia	(1898)	New Jersey
Woman's Medical College of Pennsylvania	(1890) (1902)	New Jersey
University College of Medicine	(1909)	Virginia
Trinity Medical College	(1896)	New Jersey

Mr. Wiley also reports that 6 candidates were licensed by indorsement by the Board of Regents under provisions of

Chapter 357, laws 1917. The following colleges were represented:

LICENSED BY INDORSEMENT

College	Year Grad.	No. Endorsed
Harvard University	(1888)	1
University of Minnesota	(1897)	1
Albany Medical College	(1894)	1
Jefferson Medical College	(1882)	1
Woman's Medical College of Pennsylvania	(1895)	1
Licentiate of the Apothecaries Hall of Dublin	(1887)	1

Book Notices

La Gangrène Gazeuse. Bactériologie, Reproduction Expérimentale, Sérothérapie. Par M. Weinberg, Chef de Laboratoire et P. Séguin, Boursier à l'Institut Pasteur. Paper. Price, 20 fr. Pp. 444, with 61 illustrations. Paris: Masson et Cie, 1918.

This monograph summarizes our knowledge of the bacteriology and nature of the infections now usually called gas gangrene, presenting what we knew before the war and the information derived from extensive investigations during the first two or three years of hostilities. The first part deals with the period before the war, and an effort is made to clear up so far as possible the relations of the micro-organisms described under various names as causing "emphysematous gangrene." It appears that the so-called gas bacillus described by Welch and Nuttall in 1892 under the name of *B. aerogenes-capsulatus* corresponds to the bacillus described independently in 1897 by Veillen and Zaber as *B. perpringens*, this name, which is used in France, being the first name of this bacillus to conform to the rules of binomial nomenclature. The second part describes the microbes, anaerobic as well as aerobic, of the gas infections studied by the authors as well as by others during the war. In the third part is discussed the genesis of these infections, the different forms, and their experimental production. The fourth part is concerned with the serum treatment of gas infections, a new and promising departure during the war, the final evaluation of which must be awaited. The illustrations are superior, and the bibliography is complete to October, 1917. This book is unquestionably the most valuable in its field, and will always be a great landmark in the study of gas infections.

The Newer Knowledge of Nutrition. The Use of Food for the Preservation of Vitality and Health. By E. V. McCollum, School of Hygiene and Public Health, The Johns Hopkins University. Cloth. Price, $1.50. Pp. 199, with illustrations. New York: The Macmillan Company, 1918.

In this small volume the author tells the result of nearly 3,000 feeding experiments, and correlates the results with clinical facts. As the name indicates, the book deals with the newer knowledge of nutrition, which till now has been written in technical language and scattered through technical journals. The author here digests the literature, and presents the latest opinions in nontechnical, simple language that reads as easy as a novel. This he is well able to do because he is master of the subject.

At this time, when chemistry is in the saddle, the unbiased attitude of the author, who is a chemist, is plainly stated (page 54):

> Without in the least attempting disparagement of the value of the services of the chemist in the study of the problems of nutrition, it may truthfully be said that both his ordinary, and his unusual and most searching methods for the analysis of foodstuffs fail to throw any great amount of light on the value of a food or a mixture of foods for inducing growth.

In his investigations, therefore, he used the biologic method for the analysis of a foodstuff, and in this presentation he discusses it. He considers especially growth, experimental scurvy, the vegetarian diet, foods of animal origin, diseases referable to faulty diet or deficiency diseases, the nursing mother as a factor of safety in the nutrition of the suckling, and the planning of the diet.

Funk (*Lancet* 2:1266, 1911), through the vitamin hypothesis, attempted to account for the diseases scurvy, rickets, pellagra, beriberi, etc., as being each due to the lack of a specific chemical substance, vitamin, in the diet. McCollum criticizes this term and others, showing why they are inappropriate, and supplants the term with the indefinite terms fat-soluble A and water-soluble B. These terms, however, are not final, since they are used to mean only that the deficient substance in one case is soluble in fat, and is usually found in butter, and in the other that it is soluble in water. This indefiniteness is vividly illustrated in the final page (114) of the chapter on deficiency diseases. Here he says:

> Pellagra, scurvy and rickets do not belong to the same category with beriberi. . . . There do not exist "curative" substances for these diseases. . . . The faults . . . have been shown to reside in maladjustments of and unsatisfactory quantitative relationships among the now well recognized constituent of the normal diet. They are to be sought in the quality and quantity of the protein, the character and amount of the inorganic constituents, the physical properties of the residues which are left after digestion, and form the feces from which the intestine must rid itself.

This maladjustment, he states, can be remedied by the more liberal use of milk, butter, cream, eggs and leafly vegetables which furnish fat-soluble A; but occasionally diets are encountered that contain too little of the water-soluble B. This in reality is not new to most clinicians, but is the old remedy in a different vehicle. However, the book contains much that is new, is full of suggestions, and is a distinct addition to preventive medicine.

The Wassermann Test. By Charles F. Craig, A.M., M.D., Lieutenant-Colonel, Medical Corps, United States Army. Published with authority of the Surgeon-General, United States Army. Cloth. Price, $3. Pp. 239, with illustrations. St. Louis: C. V. Mosby Company, 1918.

This book is published because the author was urged to record his experience with the Wassermann test in the diagnosis and treatment of syphilis through many years. The writer's modification of the Wassermann method, which has been used very extensively and which seems to be quite as simple and as accurate as any other method, is described fully and clearly. At the same time the most important observations in regard to the test in the literature are considered. The author emphasizes that much of the misunderstanding and confusion among physicians in regard to the value and the limitations of the Wassermann test are due largely to the fact that the test frequently is delegated to poorly trained or careless assistants, the results consequently often being erroneus and unsatisfactory. It is, of course, essential, if reliable results are to be obtained, that the test always be made by competent serologists. The last paragraph in the book may be quoted in full to show the author's opinion of the Wassermann test of the cerebrospinal fluid:

> In no case can it be stated that the syphilitic patient has been given the best that it is possible for medical science to give him, either in the way of diagnosis or treatment, if the thorough examination of the cerebrospinal fluid has been omitted; and this examination should become as much of a routine in the diagnosis and treatment of syphilis as is the Wassermann test on the blood serum.

This book is a standard authority in its field, and may be accepted with complete confidence for guidance and instruction in carrying out the Wassermann test.

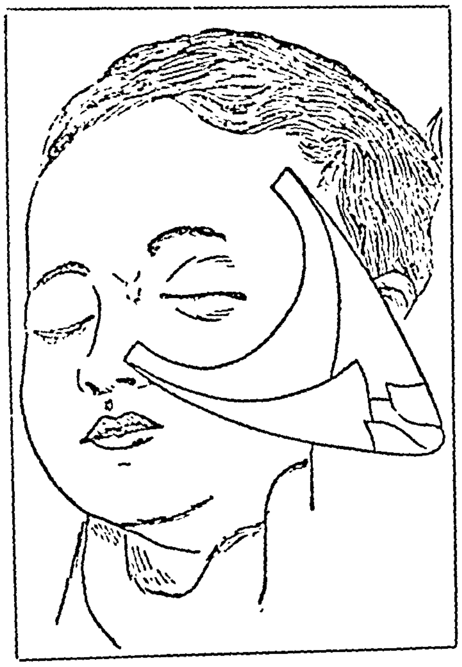
The Spleen and Anæmia. Experimental and Clinical Studies. By Richard Mills Pearce, M.D., Sc.D., Professor of Research Medicine, with the assistance of Edward Bell Krumbhaar, M.D., Ph.D., Assistant Professor of Research Medicine, and Charles Harrison Frazier, M.D., Sc.D., Professor of Clinical Surgery, University of Pennsylvania. Cloth. Price, $5. Pp. 419, with 16 illustrations. Philadelphia: J. B. Lippincott Company, 1918.

This book is divided into three parts. The first and largest consists of ten chapters by R. M. Pearce, on the effects of splenectomy. The relation of the spleen to blood destruction and regeneration, the changes in the bone marrow, the liver and the lymph nodes after splenectomy, and the effects of splenectomy on metabolism as observed in the dog as well as in man are discussed on the basis of experimental studies previously reported from time to time in medical journals and now largely rewritten. The second part, by E. B. Krumbhaar, contains clinical observations on the various forms of splenomegaly accompanied by anemia, and their diagnosis and treatment. The third part, by Charles H. Frazier, discusses the surgical treatment of diseases of the spleen, and brings out the new points in regard to splenectomy learned from its extended use in recent years. It should be noted that injuries, infections and tumors of the spleen are not considered, and that the relation of the spleen to the leukocytes is discussed only incidentally, the emphasis being on the relation of the spleen to the red cells. The thorough consideration of splenectomy as a method of studying the relation of the spleen to blood destruction and regeneration and of treatment of human diseases of the spleen accompanied by anemia, as well as of the classification, diagnosis and treatment of the noninfectious splenomegalies accompanied with blood destruction makes this a highly valuable book, of interest to all physicians in any way concerned about the diseases of the spleen.

Social Medicine, Medical Economics and Miscellany

To Protect the Clothing in Irrigating the Eye

This illustration shows how a piece of adhesive plaster can be used to form a funnel to drain away fluid used in irrigating the eye, without letting it run down to the ear and neck. The plaster is cut out to fit around the eye, and the lower corners are brought up to form the funnel. This little device has been used for several years by Dr. F. Lopez, who describes it in the *Anales de la Sociedad Oftalmologica Mexicana*, **1**:101, 1918. This new journal, by the way, publishes on separate, loose cards summaries in English and French of its original articles, ready for filing. The address is Donato Guerra 11, Mexico, D. F.



Air Conditioning in the Home

In the *Ohio Public Health Journal* for November, 1918, Emery R. Hayhurst details experiments in his own home to determine whether the average sized residence could be air conditioned, especially in regard to maintaining a proper humidity (from 40 to 50 per cent.), comfortable temperature and healthful atmosphere during the closed-up season of the year, and in a manner to be practical and feasible for the small householder. This house was heated by hot air furnace and contained several grates burning natural gas. Among the observations and deductions of the experimenter were the following: The comfortable living room atmosphere may be defined as one in which there is a barely perceptible circulation of air, yet without draft; temperature not depressingly high nor uncomfortably low, with heat more or less evenly diffused throughout the rooms; a degree of humidity which is neither high enough to be depressing nor low (dry) enough to be irritating; the absence of noxious gases, as those escaping from stoves or grates and, obviously, dust, smoke or disagreeable odors. Standardizing the foregoing, the air should move at a velocity of about 1 foot a second; its movement should be varied in direction; it need not be over 68 F., provided the degree of saturation with water vapor amounts to form 40 to 50 per cent. In air conditioning a residence, the chief problems to be considered and controlled are: movement of the air to overcome stagnation and stratification (indirect heating, as by hot air furnace, or perhaps the use, at times, of an electric fan accomplishes this); prevention or control of heat loss through direct filtration of heated air outward and ingress of cold air into the building (taking place rapidly about doors, windows and baseboards, floors, and especially chimney flue openings); direct conduction of heat through walls, window panes and floors; and loss of water vapor which may have been added to the air for bringing up humidity requirements. The question therefore reduces itself practically to one of heat and humidity control, part of which is accomplished by correct building construction, and the remainder by the usual type of hot air furnace and a humidifying device. When outside temperatures mount above the freezing point, 32 F., artificial humidification is not necessary; with the persistence of outside temperature below freezing, indirect heating methods, such as the hot air furnace, produce excessive dryness, which should be corrected. Heating of rooms by naked natural gas flames in grates results in sufficient atmospheric humidity (from 40 to 60 per cent.). With this degree of relative humidity "room comfort" is attained with temperatures as low as 60 F., though this probably does not mean any less consumption of fuel, as the extra amount is used up in evaporating the moisture which comes in contact with the heated air and the furnace box. It is, however, more healthful and comfortable, since it does away with the necessity of excessive heating (from 70 to 80 F.) in order to feel comfortable on cold days.

Revision of the Nomenclature of Diseases

The official "Nomenclature of Diseases" is drawn up by a committee appointed by the Royal College of Physicians, and is subject to decennial revision. The first edition was begun in 1859 and completed in 1869; subsequent editions have been published in 1884, 1896 and 1906. The fifth edition, which was begun in 1912, has just been published and shows many changes corresponding to the progress of medical science. For the first time three new groups of diseases are recognized: disease of the blood, diseases of the ductless or endocrine glands, and diseases due to disorders of nutrition or of metabolism. The triple column of Latin, French and German equivalents which formed a prominent feature in previous editions has been omitted. The aim of the compilers of the first edition in 1869 was "to prepare a nomenclature suitable to England and to all countries where the English language is in common use and to lay the foundations for a nomenclature of diseases in any language extant on earth." With this object they supplied for each name the corresponding Latin term, which is the language of ancient science and probably the fittest language for a nomenclature common to all the world: and also the equivalent term in the three modern languages that are the richest in medical learning and literature—French, German and Italian. The Italian version was omitted in the third edition, but the Latin, French and German equivalents were retained in the third and fourth editions. The decision to omit the foreign equivalents in the present edition was made on the grounds that the ambition of the compilers of the first edition to be founders of an international nomenclature has not been realized; it is impossible to guarantee the correctness of the French and German equivalents except by international agreement, and the insertion of the French and German names of every disease is beyond the scope of a British nomenclature of diseases. The omission of the Latin and Greek equivalents requires a more detailed explanation. It is pointed out that the Latin equivalents are very often translations of English phrases, and that many of the names of diseases in common use are framed on a Latin or Greek basis, or are hybrid combinations sanctioned by time. Such names, therefore, need not be expressed in separate Latin columns. In this volume Latin and Greek names have been incorporated in the text either as synonyms of English names or as main headings in any case in which the Latin or Greek name is more frequently used than the English equivalent. The committee express the hope that with the present simplification, the nomenclature of diseases will be generally used by all physicians for the registration of diseases, and the return of causes of death, since uniformity of terms is of the greatest importance for all statistical purposes.

Hospital Records as Evidence in Criminal Cases

(Bolden v. State (Tenn.), 203 S. W. R. 755)

The Supreme Court of Tennessee, in reversing a judgment of conviction of defendant Bolden of the murder of one George Norman, says that the only proof claimed by the state to have been made of the death of Norman was the testimony of the superintendent of a hospital to which Norman had been taken after he was shot by the defendant. The superintendent testified in substance that he produced and filed the record of George Norman as a patient in the hospital, showing by its recitals that the latter was admitted on the day of the shooting and died there six days later, the diagnosis being gunshot wound of the peritoneum. The witness knew nothing about George Norman, except what the records of the hospital showed. The witness did not make the entries in the record, but they were made at his direction, and under his control and supervision, and it was part of his duty as superintendent to see that they were correctly made. The witness did not know George Norman; had never seen him. He did not know, of his own knowledge, whether Norman was dead or not. It was insisted by the state that this was sufficient proof of the death of Norman to sustain the conviction, but the supreme court does not think so. Hospital records of the condition of patients are held to be competent evidence as entries by a third and disinterested person made in the routine of the business of the hospital. But such entries are not to be received in a criminal case, if the enterer can be produced at the trial to testify in person as to the matters he has recorded. If, however, his memory as to the facts recorded has failed, he may testify that the entries were correctly made by him at the time, and then the entries may be admitted. In this case the superintendent of the hospital did not even testify that the record was correctly kept by his subordinates, and the court is of the opinion that the testimony was incompetent. The proof offered in this case did not stand on a higher plane than hearsay. This being the only proof of the death of the person proved to have been shot by the defendant, there must be a reversal of the judgment and a remanding of the case for a new trial.

Allows Use of Saccharin in Beverages

(People v. Excelsior Bottling Works, Inc. (N. Y.), 171 N. Y. Supp. 733)

The Supreme Court of New York, Appellate Division, First Department, takes a different view of the use of saccharin as a sweetener from that of the Court of Special Sessions of the City of New York, and reverses the latter's judgment of conviction of the defendant for having in its possession and offering for sale as a beverage bottled strawberry soda, which it was alleged was adulterated, in that saccharin, a deleterious ingredient, had been used as a sweetener or substitute for sugar, injuriously affecting the quality of the soda water, in violation of the sanitary code and a resolution of the board of health. The court says that, so far as appeared, the question has not been before the federal courts for decision with respect to the use of saccharin in food products. The decision of the secretaries of agriculture, commerce and labor, and of the treasury, based on the report of the referee board of consulting experts, was intended, this court thinks, to prevent the use of saccharin as a sweetener for food products proper, such as canned vegetables, preserves and candy. It is quite evident that the secretaries were not considering the use of saccharin in beverages.

There was a label on the bottle containing printed matter, including the statement: "Sweetened with Sugar and One One-Hundredth of One per cent. of Saccharin (Benzo-Sulphinide)." The uncontroverted evidence showed that the use of soda water as a beverage containing this quantity of saccharin could not possibly be injurious to health, and that there is greater danger of injury to health from consuming too much sugar than from the consumption of saccharin in such a percentage. It also appeared that the use of sugar in any form is injurious to people suffering from diabetes and some other diseases, while the use of saccharin by them to flavor food and render it palatable is prescribed by medical authorities. The only possible theory on which such use of saccharin could be prohibited is to prevent deception, by leading purchasers to think that the food products had been sweetened by sugar, which contains a food value, and not by saccharin, which has no food value. There was in this case no evidence of deception, and the label was designed to prevent deception. Soda water is not a natural food product, but is a compound of food products, and the court is of the opinion that such use of saccharin comes within the proviso contained in Section 68 of the Sanitary Code relating to a mixture of compounds by their own distinctive name, and that the label complied with the requirements thereof. The resolution of the board of health was not enacted in form as an amendment of the sanitary code, and it could not be given effect as such. The only authority of the board to adopt resolutions with respect to the sanitary code was to carry the provisions thereof into effect. Moreover, since saccharin is not injurious to health, its use may be regulated, but cannot be prohibited, under the exercise of the police power, and therefore the court thinks the resolution was void.

If a standard of purity or with respect to the ingredients to be used in making soda water had been prescribed by the legislature, or by legislative authority, then it might well be argued that no other ingredients could lawfully be used in making it. It is perfectly obvious that, entirely aside from the question of disease or medical advice, some people may desire, especially in hot weather, a cooling beverage that contains no food value, or that has been sweetened to render it palatable by the use of saccharin, instead of by the use of sugar, and there is therefore no occasion or authority for prohibiting such use of saccharin. It follows that the conviction should be reversed, and the information dismissed.

Care Required of Injured Person

(Flint v. Connecticut Hassam Paving Company (Conn.), 103 Atl. R. 840)

The Supreme Court of Errors of Connecticut, in affirming a judgment in favor of the plaintiff for damages for personal injuries alleged to have been caused by the defendant's negligence, says that the plaintiff on the trial had offered evidence that she had sustained injuries which were permanent, that as soon as possible after the infliction of her injury she had procured medical treatment from a physician and surgeon in good standing and long experience, and that she had followed his advice and taken his treatment. The defendant offered evidence that the plaintiff did not act with reasonable care, endeavoring to cure herself of her injuries, but that, had she received proper treatment, she would have recovered much sooner. It was contended by the defendant that the trial court should have left to the jury as a question of fact whether the plaintiff had exercised ordinary care in her efforts to effect a cure. What the jury was instructed was that:

> In arriving at the amount of your verdict, you should make no deductions on any theory that she might have been cured earlier by different treatment; for, if you find that she in good faith employed such medical aid as she thought suitable and endeavored to cure herself, it makes no difference whether she used the best methods in such endeavor to cure herself or not. She should not suffer anything, or any loss, even if you come to the conclusion that any other kind of medical treatment might have effected a cure.

This instruction was erroneous, but harmless. It was the duty of the plaintiff to use ordinary care to cure and restore herself, and reckless or negligent conduct on her part, if thereby her injuries were enhanced, could not be charged to the defendant. But it did not appear that the defendant requested the court to give the jury any instructions on this question, nor did it appear what act of omission or commission on the part of the plaintiff, by which her cure was retarded, was imprudent or negligent; on the contrary, it did appear that she did do all that careful and prudent conduct required in consulting a physician of good standing and following his advice as to treatment. It would seem that the jury could not have been misled by the instruction given, although as an abstract proposition it is the law that it was not a question of good faith on the part of the plaintiff, but one of ordinary care. But the trial court correctly informed the jury "that no diminution of damages should be made, if some other kind of medical treatment might have effected a cure"—that is, always on the condition that the plaintiff exercised ordinary care in selecting a physician and the treatment she was to follow.

Thrombosis of Lateral Sinus. G. A. Moore.—p. 71.

Study of One Thousand Diphtheria Deaths.—A statistical study was made by Carey for the Massachusetts Department of Health of 1,000 deaths due to diphtheria. Twenty per cent. of the deaths occurred in children less than 1 year of age; 25 per cent. between 1 and 3 years; 62 per cent. of all deaths occured before the age of 5. Laryngeal diphtheria was far more prevalent than other forms; pharyngeal was next in order of frequency and the nasal form last. Carey believes that if the laryngeal cases were diagnosed earlier, the mortality from these cases would be lower. He urges that a culture should be taken in all conditions where there is a possibility, even though remote, for diphtheria to be suspected.

Twenty-three and one-tenth per cent. of the patients were sick a week, 4.2 per cent. were sick from one to two weeks, and 4.2 per cent. were ill several days without medical attention. Eleven and eight-tenths per cent. were found moribund on visitation by the physician. Here again is evidence for the necessity of awakening people, through educational methods, to their responsibility to their children. Sudden death occurred in 5.2 per cent. of the cases. In many instances lack of nursing care was the responsible factor. Another factor in the sudden death group appeared to be the repeated attempts at intubation where, for some reason, the tube was either not properly introduced or else expelled.

The dosage of antitoxin was extremely varied in amount, the number of doses given, and the interval between dosage. In twenty-nine instances, it was found that less than 3,000 units were administered. The amount increased from this to a point where a young child of 3 years received 225,000 units. The usual doses, however, seem to have been from 6,000 to 9,000 units. The number of doses varied from one to several on consecutive days and in a few instances it was administered every four hours until death occurred. In one instance 80,000 units were given in this manner. In no instance was antitoxin given intravenously. Carey urges that particular stress be laid in the instruction of medical students on the necessity of properly administering antitoxin, thus avoiding the chances for anaphylactic reaction and impressing on them the need of early and sufficient treatment.

Trinitrotoluene Poisoning. H. Odland.—p. 63.

Liquid-Tight Closure and Treatment of Infected Wounds.—The Taylors have devised a water tight dressing by means of which one is enabled alternately to fill and evacuate a deep wound; to fill it even to its remote recesses with irrigating fluid under positive pressure and to empty it again under negative pressure. These alternating pressures set up an ebb and flow current within the cavity of the wound and its ramifications, with the result that, with each cycle, the consistency of the pus becomes rapidly reduced. A greater and greater dilution of pus is effected at each flushing of the wound—a dilution progressing geometrically—until finally the effluent grows clear and the lining granulations clean. The authors have found that thirty-six hours is the average time required to cleanse a wound of pus. On removal of the appliance at the end of this period, clear fluid alone can be expressed from the wound and its sidetracks. The suppurative processes have not been brought to a standstill, but pus is carried away as quickly as it is formed; the solution is being brought into contact with the granulations lining the walls of all parts of the wound cavity, and bacteria, not embedded in the tissues, are rendered inert through dilution.

Autoserum Treatment of Chorea.—The treatment employed by the authors consisted of the injection into the lumbar cord region of about 20 c.c. of blood serum obtained from 50 c.c. of blood withdrawn from the median basilic vein. Of twenty-three patients so treated, 77 per cent. were cured, 19 per cent. improved and one unimproved, this one having refused further treatment on account of a severe reaction. There has been no recurrence so far. In all instances, except six in which tonsils were removed, there were observed what were apparently foci of infection, which were attended to after the course of treatment. Of the twenty-three cases, seventeen were of a mild degree and five were severe. In four instances the duration of the disease was over a year, while the remainder showed symptoms on an average of six and a half weeks' standing. The average number of injections given were three; several patients were given only one injection, while in one instance five injections were administered before a cure was affected. The average amount of serum injected was 17 c.c. Nineteen patients were cured in three weeks and four were cured within one week. All the severe cases required more than one injection. In practically every instance there had been previous medical treatment given with the usual indifferent and unsatisfactory results. In most cases there was a mild reaction in the form of vomiting and an occasional rise of temperature; on only one occasion was the reaction of such a nature as to prevent the return of the patient to the clinic and that owing to parental objection. The withdrawal of an amount of spinal fluid equal to that of serum injected did not appear to be necessary.

Effect of Dry Heat on Blood Count.—Animals subjected to dry heat for a short period show a sharp fall in the total white blood count, both the polymorphonuclear leukocytes, and the lymphocytes taking part in the fall. Following this there is a slow recovery on the part of the polymorphonuclear leukocytes, which generally require several weeks to regain their normal number. The lymphocytes rise rapidly after the initial fall and continue to rise for 2 or 3 weeks. This increase often amounts to a gain of over 200 to 300 per cent. above the normal count for the animal. These observations were made on mice, rats and guinea-pigs. The circulating lymphocytes during the more active stage of stimulation after heating show numerous examples of amitotic division. The source of the heat in these experiments was an electric bulb of frosted glass, giving the maximum heat of the amount of light generated. The method of application varied with the size of the animal and its ability to stand the higher temperatures.

Lymphocytosis Induced by Means of Heat.—A striking number of mitotic figures have been observed in the germinal center of the spleen and lymph glands during the regeneration of the cellular elements of these organs after the destructive effect of heat. This enhanced cell proliferation is interpreted by Nakahara as more than compensating for the degenerated cells, because of the subsequent enlargement of the organs. It has also been pointed out that the characteristic decrease in the number of lymphocytes immediately after the heat treatment is always accompanied by an extensive cell degeneration in spleen and lymph glands at the corresponding period. On this basis it seems evident that the pronounced lymphocytosis induced by means of heat treatment of the animal is due, at least in part, to the enhanced proliferative activity of germinal centers in the spleen and lymph glands, reacting to the destructive effect of heat on lymphoid cells.

Lymphocytes in Resistance to Transplanted Cancer.—The experiments made by Murphy and Sturm, carried out on over 100 mice, show that animals whose lymphocytes have been stimulated by dry heat have a much higher resistance to transplanted cancer than control mice inoculated with the same tumor. The general health of animals subjected to this treatment did not seem in the least affected. This difference in resistance was manifest both when the tumor inoculated gave a relatively low percentage of takes, and when the tumor was highly virulent and gave a high percentage of takes.

Lymphocytosis and Growth of Spontaneous Tumors in Mice.—Spontaneous cancers were removed from a series of mice by operation. The animals were then subjected to an exposure to dry heat at a temperature ranging from 55 to 63 C. for five minutes. Immediately afterwards a graft of the original tumor was returned. The mice so treated exhibited a marked increase in their resistance to the growth of the cancer graft, over 59 per cent. remaining entirely free from a return of the cancer. In a control series in which no treatment was given 96 per cent. of the animals showed a return of the cancer.

Lymphoid Tissue and Resistance to Experimental Tuberculosis in Mice.—Mice with high lymphocyte counts and increased activity of the lymphoid tissue induced by one exposure to intense dry heat exhibit a marked increase in the resistance to large doses of bovine tubercle bacilli as compared with that shown by control animals given a similar inoculation. This resistance, judged by the time of survival after inoculation, is increased from two to threefold.

Effect on Lymphocytes of Exposure to Sun.—Chronic solar dermatitis was accompanied, in twenty-five of thirty-eight individuals studied, by Taylor by an appreciable increase, percentage and absolute, in the number of circulating lymphocytes. In eight there was a definite decrease and in five no appreciable change after prolonged exposure to the rays of the summer sun. Of the thirteen subjects with no increase in blood lymphocytes, six failed to tan, three were so dark originally that to determine an increase was impossible, and five had an extremely high lymphocyte count at the first count. Blood counts on white persons living in the Philippines indicate that the blood lymphocytes are likewise increased after a prolonged period of residence in the tropical zone. Because of the parallelism between the tanning and the blood changes it seems probable that the lymphocytosis observed in the majority of instances, which is similar to the response of the blood of animals to small doses of the roentgen rays, is due to the effects of the ultra-violet rays contained in the solar spectrum.

Roentgen-Ray Effects on Blood Cells.—The authors found that roentgen rays in large doses affect the lymphocytes before any of the other circulating cells. There is a sharp fall in the total number of circulating lymphocytes, which is complete forty-eight hours after roentgen-ray treatment. Following the immediate decrease in the circulating lymphocytes there is a primary rise, followed by another fall, which in turn is followed by a permanent rise of these cells to normal. The polymorphonuclear neutrophilic leukocytes, when affected at all, increase in number immediately after the administration of the roentgen rays and then tend to decrease below their normal level. This decrease is followed by a return to normal many days before the lymphocytes reach their original level. The other cells of the blood follow the neutrophilic curve.

Roentgen-Ray Effects on Lymphocytes.—Blood counts were made on nine rabbits after an exposure to roentgen rays of a seven-eighths inch spark-gap, milliamperage 25, distance from the target 8 inches, and time of exposure twenty minutes. In seven of the nine animals there resulted an increase of the circulating lymphocytes. In five of these the increase was marked and in two others definite but not striking. Of the two animals which showed no stimulation one showed marked fluctuation of counts both before and after roentgen rays and the other little or no change. The higher penetrating dose (6 inch spark-gap, milliamperage 5, distance from the target 10 inches, times twenty-six minutes and fifty-seven seconds) given to two animals produced no appreciable stimulation.

Roentgen-Ray Effects on Lymphoid Tissue.—The small dose of roentgen rays (spark-gap seven-eighths inch, milliamperage 25, ditance 8 inches, time twenty minutes) applied to the rabbit has no appreciable destructive effect on the lymphoid tissue. Indications of stimulation of the lymphoid tissue appear immediately after the treatment, become most pronounced in two (in lymph glands) to four (in the spleen) days, and persist, in a slight degree, up to the fourteenth day. These facts suggest that the lymphocytosis induced by the small dose of roentgen rays is due to a primary stimulative effect on the lymphoid tissue of the animal.

Roentgen-Ray Effects on Tumor Cells.—The direct action of roentgen rays in more powerful doses than can be applied therapeutically the authors found to be somewhat injurious to tumor cells, but by no means destroying them. In fact, the cancer cells establish a resistance to the roentgen rays after repeated doses. This harmonizes with the experience of clinicians who have succeeded in checking cancerous growths for some time but reach a point where no response can be effected by repeated doses. The rays of low penetration are apparently more harmful to tumor cells than the more penetrating rays.

Blood Counts in Experimental Poliomyelitis.—Blood counts were made on six series of monkeys before and at various intervals after the injection of active poliomyelitic virus. From the data thus obtained the variations in the circulating white cells have been followed in the several stages of the disease (*a*) before injection, (*b*) during the incubation period, (*c*) during the acute stage, including the stage of prostration, and (*d*) during recovery. Averages of 121 counts on forty normal monkeys are recorded. Immediately following the injection of the virus the relative and actual numbers of lymphocytes are slightly diminished. In many cases the curve continues sharply downward. In others from the fourth to the sixth day there is an actual increase for a brief period to a point somewhat in excess of the original count. With the onset of symptoms a lymphocytic crisis takes place. The curve then continues slightly downward, while the polymorphonuclear neutrophilic leukocytes are relatively and actually increased to approximately the same time. During the stage of prostration the curve of the polymorphonuclear neutrophilic leukocytes returns to almost normal, while the lymphocytic curve continues slightly downward. With recovery the lymphocytes slowly return to normal after several weeks. There is no evidence of lymphocytic stimulation after recovery. Eosinophilic, basophilic, large mononuclear, and transitional leukocytes follow the depressions and stimulations exhibited by the neutrophilic cells of the same series. These results are consistent with the observations of Peabody, Draper and Dochez on human cases. The increase in the total number of circulating lymphocytes after the lymphocytic crisis is coincident with the passing of the acute stage. Additional evidence is presented to indicate that Smillie produced atypical but definite poliomyelitis in the monkey with cultivated virus.

Effects of Roentgen Rays on Poliomyelitis.—In two series of the experiments here recorded the monkeys which had been repeatedly exposed to roentgen rays responded with typical acute poliomyelitis to an intracerebral inoculation of poliomyelitic virus filtrate, whereas, the normal control receiving the same dose showed no symptoms. In another series the roentgen-rayed animal came down with typical poliomyelitis after inoculation with three fourths of the dose which was not infective for the control. It has been demonstrated that roentgen rays diminished both the number of circulating lymphocytes and the resistance of the animal to the weak poliomyelitic virus. Whether the lowered resistance of the animals as the result of the treatment with roentgen rays is due to the reduction of circulating lymphocytes in each of the roentgen-rayed monkeys is not determined in these experiments. However, the great reduction in lymphocytes in human cases and in monkeys during the acute stage of experimental poliomyelitis and the gradual return of the cells to their former numbers during recovery strongly suggest a definite relation between these cells and one factor of resistance in poliomyelitis. On the other hand, the reduction in resistance by roentgen rays, while definite, is not sufficiently great to warrant the conclusion that we are dealing with major factors governing infection or noninfection. Another experiment in this paper deals with the survival of a subinfective dose of the virus in the normal monkey brain. A monkey receiving the subinfective dose of the virus was exposed to roentgen rays at twenty-eight days, another at fifteen days after injection, but neither animal showed symptoms of poliomyelitis. It is concluded that within this period the virus did not remain unchanged in the normal monkey brain. An attempt to reduce the immunity in a monkey acquired by an attack of experimental poliomyelitis was unsuccessful.

Action of Chlorinated Antiseptics.—This work demonstrates that the chlorinated antiseptics have no power to penetrate blood clots and destroy bacteria therein contained. Correspondingly, blod clots may protect virulent bacteria for a long period of time and the organisms properly planted will be able to proliferate in a normal manner. The authors used neutral solution of chlorinated soda, chloramine-T solution, calcium and sodium chlorid and eusol.

Breathing Gymnastics for Marching Soldier.—Van Baggen advocates breathing gymnastics for the marching soldier for the purpose of developing the chest, strengthening the muscles of the thorax, and fortifying action on the pulsation of the heart because they are evidently of great advantage for those who are obliged to exert their physical capacities to the utmost. Moreover, control over the breath, which means the regulation of inspiration and expiration, is most valuable while walking, marching, running, and, in general, while performing any bodily exercise. It has been found also that the exercises have an excellent influence on the correct erect bearing of the men.

Operation for Prolapse of Rectum.—The method used by Barss, but not original with him, consists in making small puncture incisions about half an inch from the anal margin—one anteriorly, one posteriorly, and one on each side. Through these small cuts scissors are introduced and blunt dissection conducted beneath the skin so as to connect each puncture, and thus make a complete subcutaneous ring around the anus. Through the anterior puncture silver wire (gage 19) is threaded on each side, the two ends appearing through the posterior cut. The wire is then drawn up and twisted so as to contract the anal opening to a size which will just admit freely the index finger. The ends are twisted, the excess wire cut and the ends tucked beneath the skin. The punctures are so small that sutures are not needed. The wire is completely buried. A sterile pad is the only dressing applied.

Peanut Bronchitis.—Cases are cited by Patterson to illustrate the characteristic train of symptoms which follow the inspiration of fragments of peanut into the respiratory tract and which continue until the fragments have been removed bronchoscopically or evacuated spontaneously and the pus which follows its sojourn in the bronchus has been evacuated bronchoscopically.

Pulmonary Tuberculosis and Insanity.—Among 962 necropsies performed at the Manhattan State Hospital, in 131 cases, or 13.61 per cent., the lesions of active pulmonary tuberculosis were found. In 107 cases, or in 11.12 per cent., a clinical diagnosis of pulmonary tuberculosis was ventured, while in eighty-one out of the 107 cases, or 76.35 per cent., the diagnosis of pulmonary tuberculosis was corroborated at postmortem examination and in twenty-six of the 107 cases, or 23.65 per cent., no corroborative evidence of tuberculosis was found at necropsy. Of the 131 cases of active pulmonary tuberculosis found at necropsy, eight-one, or 61.83 per cent., were correctly diagnosed antemortem, and fifty, or 38.17 per cent., were not clinically suspected as tuberculous. Sands says that psychoses among tuberculous patients are infrequent and are, usually, either of the infective toxic type of reaction, or shown by the manic depressive behavior. Psychoneurosis, especially of the neurasthenic and of the spychasthenic types, is quite prevalent among tuberculous patients. The general therapeutic principles employed in the treatment of tuberculosis are equally applicable in the insane as in the mentally sound patients afflicted with the disease.

Cure of Cancer of the Skin.—Bowen believes that every case of cancer of the skin can be cured, and perhaps prevented, but whether or not any individual case is cured, depends on how soon a correct diagnosis is made, on how soon proper treatment is begun and on the thoroughness of the treatment. Small lesions can be removed by caustics, fulgeration, roentgen ray, radium or operation. The larger lesions can be removed by fulgeration, roentgen ray, surgery or a combination of these methods. No single method will suit all cases, but with the proper selection of methods at our disposal Bowen says "nearly" every case of skin-cancer can be cured permanently.

Prevention of Acute Respiratory Affections.—During the period prior to the war Beveridge says accommodation in barracks and hutments in Great Britain was provided on the scale of 60 square feet or 600 cubic feet per man. On the outbreak of the present war the great influx of recruits necessitated a somewhat less generous provision, and having regard to military exigencies, 40 square feet or 400 cubic feet was fixed as the minimum accommodation which could safely be permitted in quarters. This has since come to be regarded as a war time standard. The distance between beds is of paramount importance and quite a moderate degree of "spacing out" of beds combined with simple methods for improving ventilation is highly effective in reducing carrier rates. Infectious diseases affecting the respiratory passages are largely spread by "spraying" from the nasal and buccal orifices of infected persons, so that the chances of a healthy person in the neighborhood becoming infected increase enormously the nearer such a person is to an infected individual. In addition, inadequate ventilation permits of a great concentration of infective material in the surrounding air which increases the chances of transmission of infection.

The important elements in "overcrowding," so far as the spread of infectious disease affecting the respiratory passages is concerned, are, therefore, proximity of heads and defective ventilation. Ventilation may be improved within the limits short of creating a draught, but satisfactory results can only be expected when close proximity of heads is also prevented. Proximity of heads and degree of ventilation are, therefore, the criteria by which the adequacy of accommodation should be judged.

In calculating cubic space in quarters, heights above 10 feet are neglected as not contributing useful space so far as the prevention of true overcrowding is concerned. In hutments the cubic space above 10 feet from the floor is usually relatively small and for practical purposes may be neglected. On this basis the floor space expressed in square feet is numerically one tenth of the cubic space, so that accommodation may, for simplicity, be expressed in terms of square feet of floor space. Where huts are about 20 feet wide, as is commonly the case, and men sleep down each side of the linear wall, space per man is numerically a tenth of the floor space per man and affords a ready and rapid guide as to the sufficiency of accommodation. In ordinary hutments, therefore, 400 cubic feet, or 40 square feet of floor space, or 4 linear feet of wall space per man, may be regarded as affording the same accommodation. Accommodation in tiers is not recommended where it can be avoided; it may be necessary in forward areas but in no case should more than two tiers be countenanced unless for very short periods and on grounds of military urgency. In ordinary hospitals 60 square feet of floor space with 6 feet of wall space per patient is provided, but during periods of pressure this may have to be reduced to 5 feet of wall space. In hospitals for infectious disease 100 square feet of floor space is allowed.

Protection against cold and inclement weather in the shape of warm and waterproof clothing has a marked effect in preventing a lowering of resistance, and in this connection the importance of providing efficient drying rooms at all camps and billeting areas cannot be overemphasized. Such drying rooms may be heated by coke or coal stoves, or the heat from incinerators may be utilized. In order to maintain resistance to disease and to mitigate its severity when contracted, a sufficiency of good and well-cooked food is essential.

Acute Respiratory Infections Among Colored Troops in French Army.—Borel's observations show that among the French black colonial troops acclimatization and vaccination were the two factors of value in producing immunity against pneumonia. Seven thousand men, who had already been acclimated for two or three years, were immune to such an extent that only two deaths resulted from pneumonia. Senegalese who had been in contact with the pneumococcus for one year and who had gone through epidemics at the time of their arrival in France were, it appears, spontaneously vaccinated. A colored contingent of 600 men, who arrived in the midst of an epidemic of pneumonia was vaccinated and apparently with perfect result.

Experience of American Expeditionary Forces with Respiratory Infections.—Of the 1,613,500 days lost in the American Expeditionary Forces up to June 1, 1918, from all causes—sickness, accident, injury in action and other traumatisms—Emerson finds that 1,481,000 days, or 91.78 per cent., were lost because of sickness. Of the total loss of days due to hospitalization from sickness 631,226 days, or 42.61 per cent., were due to eleven communicable and respiratory infections, the average number of days lost for each case of the diseases, respectively, to be as follows: pneumonia (lobar), 22.7 days; meningitis (meningococcus), 20.7 days; scarlet fever, 14.8 days; mumps, 12.0 days; pneumonia (broncho), 11.7 days; measles, 10.3 days; diphtheria, 7.2 days; bronchitis (acute), 6.3 days; pharyngitis (acute), 4.3 days; tonsillitis (acute), 4.1 days; influenza, 3.4 days. Among the causes which are known to have contributed to the high incidence of the diseases in question are crowding in camps, in trains, on transports, at ports of embarkation and in barracks; exhaustive drilling, working and sleeping in wet clothing and shoes; eating of food served cold, insufficient blankets for warm sleeping; habitual neglect of open window ventilation of barracks; spitting promiscuously and failure to protect the nose and mouth when coughing and sneezing among groups of men.

Acute Respiratory Infections.—To prevent pneumonia of the lobar type, Binsser says one must not only prevent contact but remember that the most important thing is to avoid reduction of that resistance which naturally is very high in all human beings, and that one is dealing with a matter which requires careful hygiene and sanitation. The most important of all is the question of ventilation and air space. The normal resistance of a human adult is much less complete against streptococcus infections than against pneumococcus infections. In an epidemic of 701 cases of pneumonia, 389 patients did not have measles. Of these ninety-three died. The death rate of primary pneumonia was 12 per cent., and the death rate of cases following measles was 29.8 per cent.

Bone Grafting in Gunshot Fractures of Jaw.—The authors are opposed to fixing bone grafts or fragments by plates and screws, by wiring, or even by dovetailing the graft into the fragments, because the presence of foreign bodies greatly militates against successful healing, a sinus down to the plate or wire almost invariably forming. Their practice now is to keep the graft in place by sewing the soft tissues closely over the graft and the ends of the fragments by hardened catgut. This has the additional advantage of closely surrounding the graft with living vascular tissue and abolishing dead spaces in which blood clot and serum can collect. This improves the nutrition of the graft and diminishes the risk of sepsis. The skin is approximated with a few interrupted stitches. No drainage is employed beyond that of leaving spaces between the skin sutures to allow the escape of serum. A simple dressing and bandage is applied.

Use of a Vaccine Made from Influenza Bacillus.—Over 100 cases of chronic infection by the bacillus of influenza have been studied by Robertson. In nearly all of these cases therapeutic immunization has been carried out. The focal and general reactions produced, and the successful therapeutic results that have been obtained Robertson regards as being consistent only with the view that the bacillus from which the vaccines were prepared was the chief cause of the catarrhal conditions from which the patients were suffering. Correct therapeutic doses commonly caused distinct focal reactions; overdoses were followed by the development of symptoms simulating those of influenza. A continuation of correct therapeutic doses over a period of from six to ten weeks almost uniformly resulted in complete recovery from the malady. If the bacillus of influenza had not been the chief cause of the ailment, the author is convinced that these results could not have been obtained.

In the treatment of acute influenza, therapeutic immunization acts, in Robertson's experience, with equal success. A dose of 0.02 mg., repeated after twenty-four hours, generally causes the temperature to fall to normal within forty-eight hours. It is of advantage to use sensitized vaccines in acute cases. For the purposes of the preparation of these sensitized vaccines, two sheep are kept immunized against bacillus influenza. The administration of a sensitized vaccine is followed by comparatively little reactive disturbance. Robertson believes that the most convincing evidence of the causal relationship of Pfeiffer's bacillus to influenza can be obtained from the phenomena that may be observed in the carrying out of the protective inoculation. He made a number of these inoculations at the time of the summer epidemic; none of the persons contracted influenza. Robertson gives at intervals of from two to three days, successive doses of about 0.03 mg., 0.06 mg. and 0.12 mg., or two doses of 0.04 mg. and 0.12 mg. The smaller doses are given first in order to create a certain degree of tolerance of the toxin before the full dose required for complete protection is injected, and to provide against the possiblity of hypersensitiveness, which occurs in all persons who are suffering from a chronic infection by the bacillus. After each of these doses most persons within twelve to twenty-four hours experience in mild degree the symptoms of influenza. If the dose of 0.12 mg. is given at once, severe disturbances are generally experienced.

Cholesteatoma of Lateral Pharynx. J. J. Kyle.—p. 366.

Schultz's Monochord for Testing Hearing.—Recently the Otological Section of the Royal Society of Medicine approved a "standard" scheme for the testing of the hearing; in that scheme the determination of the range of hearing was included, and it was suggested that Galton's whistle or the monochord should be used to investigate the upper limit of the range. Mollison endeavors to establish the claims of the monochord over the Edelmann-Galton whistle, as an instrument of greater precision. The monochord consists essentially of a steel wire stretched between projections at either end of a steel bar; on the bar is a "bridge" which grips the wire and thus can vary the effective length of wire; for convenience the bar is provided with a handle. In practice the wire is 50 cm. long, and the bar is marked off in centimeters; this length of wire does not give low enough notes for all cases; to meet this a longer frame can be made. The wire is a steel wire (a "banjo wire") gage 26. The notes are produced by rubbing the wire in its length with a piece of wool soaked in methylated spirit or turpentine; the wool is held between the finger and thumb, and the wire pinched while the wool is pulled along the wire. An alternative method is to use a piece of chamois leather coated with powdered resin, but this is not quite so easy to use. For the highest notes a short, hard rub is best, for lower notes a lighter rub, and one on that part of the wire nearer the bridge gives a clearer and cleaner note. It is easier to produce clear notes with a heavy frame. The advantages of this instrument are said to be: (1) It is easily standardized. (2) It is simple to use. (3) By placing the support of the wire on the mastoid process the upper tone limit through bone can be tested.

Lethargic Encephalitis.—Buzzard calls attention to the fact that there is a form of encephalitis which has the constitutional disturbances, the age incidence, the seasonal exacerbations, the sporadic and epidemic types and the immunity from second attacks which are shared by measles, scarlatina, and other acute specific fevers, and that it presents an inflammatory lesion of a particular tissue in the same way as typhoid, diphtheria and smallpox display inflammatory lesions of other tissues. This form of encephalitis has been shown to be due to the virus of poliomyelitis and it should be noted that the disease is an acute one running its course in a few days, but often leaving permanent results in the form of paralysis, mental defects and epilepsy. Lethargic encephalitis, which has attracted notice this year is a distinct disease of a second group. In a third group of cases the force of the inflammation is spent on the cerebral cortex, and gives rise to considerable difficulty in diagnosis, especially in regard to the possible presence of cerebral tumor, cerebral abscess, or cerebral hemorrhage.

Buzzard cites four cases belonging to this group. All four patients were over 40 years of age, but none of them presented cardiovascular changes suggesting the possibility of cerebral hemorrhage as a diagnosis. In none of the four cases did the clinical history conform closely to that of cerebral hemorrhage, but suggested some more subacute lesion, and naturally gave rise to the question of abscess or syphilitic thrombosis. In all four cases the Wassermann reaction of the cerebrospinal fluid was negative. The lesson to be learned from the experience is that patients over 40, and even over 50 years of age may be the victims of encephalitis, producing the general symptoms of hemiplegia, aphasia, hemianesthesia, or hemianopia. In the second place, a naked eye examination of a brain on a postmortem table is not sufficient to discriminate between an ordinary cerebral hemorrhage and a hemorrhage which is only an accidental occurrence in the course of an encephalitis. When there are no obvious gross signs of disease in the cerebral arteries to account for a hemorrhage, it is essential that microscopic investigation should be carried out in order to determine the cause for the blood extravasation. Third, the presence of thrombosed cortical veins associated with hemorrhage in the neighboring brain substance is strongly indicative of an inflammatory process.

Blood Pressure and Physical Fitness of Soldier.—Sorapure suggests that the presence and relative lengths of the various phases ordinarily recognized between the systolic and diastolic pressures is of wider clinical significance than the height of the systolic pressure alone, or even that of the systolic and diastolic readings compared. He claims that it is quite a common experience to find an obviously inefficient heart giving what is accepted as a normal systolic and diastolic blood pressure reading. He has never seen a case such as this which showed all the phases in anything like the suggested normal proportion. An analysis of the blood pressure findings in a group of 769 soldiers (Guardsmen) during the twelfth week of training, showed that the most constant factor, the diastolic pressure, is for all ages somewhere between 70 and 90; that the systolic pressure should be about 50 or 60 per cent., higher than this; that the range of pressure between the two should be capable of differentiation into three different phases—the first, or first tonal, being 20 per cent. of the whole; the second or murmur phase, 40 per cent., and the third, or second tonal, 40 per cent. These findings are characteristic of the fit man.

An analysis was made of a group of 189 men, all of whom had been invalided home from abroad, but included none of organic heart trouble. Practically all showed, or had showed, evidence of autonomic disturbance of the cardiovascular mechanism (D. A. H.). Certain features in the group stand out clearly: (1) The very high percentage of the men who do not show all the phases and the greater instability of the diastolic pressure. (2) That even those who showed all phases show quite a remarkable variation in the relative proportion of these as compared with the first group. The best groups in this table, namely, ages 29 and 36, compare most unfavorably with the worst groups of the first table, namely, ages 37 and 39. The conclusions are: (*a*) that the men who are less efficient than normal do not show the characteristic phases which prevail in the first group; (*b*) that those who are physically fit show these phases in the majority of readings; (*c*) that the result of this simple test is a factor worth considering in estimating the physical capacity of an individual.

Complement Fixation Test in Tuberculosis.—The percentage of positive reactions obtained by Fidlar in his investigation in active pulmonary tuberculosis was about 75.5. The strong reactions occurred most frequently, as would be expected, in active tuberculosis, 35 per cent., in incipients, 37 per cent., in the moderately advanced, 48 per cent., in the advanced. Of 215 clinically nontuberculous cases the fixation test was positive in 21.8 per cent. Eight per cent. of the cases of tuberculosis gave a positive Wassermann, hence the proportion among tuberculous soldiers is practically not greater than occurs in the civilian population.

Bacteriology and Pathology of Influenza.—Over 100 patients were examined by Whittingham and Sims as regards the micro-organisms present in the posterior nasal swabs and sputum. The urine of these patients was also examined on several occasions. Blood cultures were performed on only the first fifty cases. The results show that there is septicemia in some of the cases. Most of these have a fatal issue. It was impossible to state definitely whether this septicemia is present early in the disease or only as a late symptom. That it is a late symptom is borne out by the fact that streptococci were isolated from the heart's blood after death in cases where the blood culture was negative early in the disease. The causal micro-organism of the septicemia is not the same in all cases. The examination of sputum and posterior nasal swabs showed a mixed and fairly constant flora. Such organisms as streptococcus, pneumococcus, *M. catarrhalis* and *B. influenzae* were present in a high percentage of cases; in all instances over 66 per cent., except in that of *B. influenzae* (46 per cent.). The predominating organism varies, being: *M. catarrhalis* in 34 per cent., streptococcus in 30 per cent., pneumococcus in 26 per cent., *Staphylococcus aureus* in 8 per cent., and *B. influenzae* in 2 per cent. of the cases. In only one of this series of cases was Pfeiffer's bacillus found to be the predominating organism.

Postmortem examinations showed lung lesions in all cases, varying from congestion and edema to pneumonia and pus formation. Invariably the picture was that of a marked toxemia, e. g., congestion and petechial hemorrhages of serous and mucous membranes, cloudy swelling and fatty changes of liver, kidney and cardiac muscle, and in two an acute nephritis. The micro-organisms isolated from lung, pleural and peritoneal lesions, blood and spleen coincide closely with the mixed flora obtained before death. Only in one case was the *B. influenzae* found in the lesions. Isolation of diplostreptococci from the heart's blood and spleen postmortem supports the view that a true septicemia is present.

The daily leukocyte counts show that all cases do not conform to one type. Broadly speaking, a leukopenia, if continued, is of bad, a leukocytosis of good, prognostic import. A marked leukocytosis after the eighth or ninth day, especially if the eosinophils are much decreased or absent, strongly suggests complications. Incomplete recoveries and the oncoming of a relapse can often be diagnosed from the blood picture, even when the clinical signs are slight or absent.

Prophylactic vaccination on two, preferably on three, occasions with a weekly interval between each inoculation is without risk, increases the immunity of the individual, and prevents the onset of pulmonary complications. Should the inoculated develop influenza, the course of the disease is invariably mild.

As regards treatment, the authors recommend that: (1) In very early cases a full dose of prophylactic vaccine should be administered. No further doses to be given, at least for several days. (2) Cases can be seen on the first day, or later, provided the temperature falls to normal, unless symptoms become worse. (3) Those cases which show high pyrexia or toxic condition from the start should be treated with polyvalent antistreptococcus serum, 20 c.c., administered subcutaneously as soon as possible, and followed by daily injections of 10 c.c. for three or four days. With this treatment calcium lactate, 5 grains, should be given daily for seven to ten days to ward off serum sickness. Vaccine may be combined with this, if required. Other forms of treatment may be combined with the above.

Vaccines in Acute Influenza.—Admitting that it may be argued that vaccine has no curative action in acute diseases, Ynn is convinced from a study of his cases that, at least, it does no harm. A constant feature has been the drop in temperature following an injection. In acute lobar pneumonia the respirations are slowed pari passu with the temperature and pulse. In influenzal bronchopneumonia, if the respirations are rapid they are slowed with the fall of temperature, but in the serious cyanotic cases with slow respirations, the rate is increased. At first the respiratory center is depressed, but with improvement come stimulation of the center before it returns to normal. The results obtained in influenzal bronchopneumonia are similar to the results obtained for several years in acute lobar pneumonia and other types of bronchopneumonia.

Bacteriology of Recent Influenza Epidemic.—Cultural examination of the aseptically obtained lung juice from a case of "influenza" eight hours after death gave an organism resembling *B. pestis* in appearance and staining characters, but isolation and growth are far more difficult than with *B. pestis*. The same organism was isolated from the throats of "carriers"; in two cases of death from this "influenza" the Klebs-Loeffler bacillus was recovered from the lung. Aphonia had been a symptom in one of these cases.

*Traumatic Obliteration of Arteries. Babinski and Heitz.—p. 481.
*Hypertrophy of Heart in Aviators. G. Etienne and G. Lamy.—p. 510.

Traumatic Obliteration of Arteries.—Babinski and Heitz tabulate the details of 106 cases of obliteration of an artery from a war wound, classified according to the artery involved and outcome of the case. If the limb is immersed in a hot bath for a certain length of time, the oscillometer findings come to approximate those on the sound side if the obstruction to the flow of blood is merely a vasomotor phenomenon. There is no change in the findings under the hot bath test if there is actual obliteration. Collateral circulation may in time overcome the effects of the obliteration. A difference of more than 1.5 cm. mercury between the systolic pressure on symmetrical points in the two limbs is pathognomonic of obliteration of a main artery if an aneurysm can be excluded and the limb is normally developed. In certain rare cases the circulation several months and years later finally approximated normal, but in a larger number two years later there is still a difference of from 3 to 6 cm. mercury between the pressures. The majority are between these extremes. In a large proportion of the total cases the obliteration was the result of a ligature applied to the artery to arrest hemorrhage.

Conservative Surgery of the Adnexa.—D'Ernst states that time enough has now elapsed since Beuttner in 1908 first applied his transverse wedge excision of the uterus for removal of diseased adnexa for its advantages to be thoroughly established. Recent reexamination of the forty cases in which the method was applied between 1908 and 1914 shows highly satisfactory results, both immediate and remote; menstruation was not interfered with and there has been no return of genital disturbances and nothing to suggest the premature menopause. The various steps of the operation are shown in seven plates. The method is designed for young women as it aims to leave most of the uterus and at least one ovary or part of one. The transverse laparotomy and preventive ligation of the uterine and ovarian arteries are followed by the excision of a transverse wedge in the fundus of the uterus. This wedge represents the continuation across the uterus of the axial line of the adnexa. When the wedge has been excised, it is cut in two along the median line, and the two halves are turned back on each side, and the lips of the gap in the uterus are sutured together. After this, the adnexa are removed as indicated, but always with care to leave one or part of one ovary. A somewhat similar method was published by Blair Bell in 1913, but it does not include the hemisection of the excised transverse wedge, while Beuttner regards this as important as it permits access to the adnexa from the median line outward and from below upward. There were five deaths in this series of forty but the cavity of the uterus could not be incriminated in any instance; in one case the simultaneous appendicectomy was evidently a factor in the fatal outcome. In the others the extent of the inflammatory lesions or a cureting done shortly before, or the clandestine use of liquor was evidently responsible. In later series of cases and in the experience of others who have applied this technic, there have been no fatalities to date.

Placenta Praevia.—Boquel advocates abdominal cesarean section when severe hemorrhages during a pregnancy are endangering life. In a case reported the woman was at the fifth month, the cervix long and without any tendency to dilate, and the hemorrhages from placenta praevia had brought her into a serious condition. The high cesarean section showed the uterus normal, and it was left undisturbed after extraction of fetus and placenta. The woman has passed through two normal pregnancies since, with healthy children. The fetus is unable to develop normally when there are recurring grave intra-uterine hemorrhages, and the high section leaves the normal uterus ready for further pregnancies. Boquel remarks that his case is the fourth that has been published in France of cesarean section for placenta praevia, while in 1913 Döderlein had compiled 146 cases in the other countries.

Curvature of the Spine in the New-Born.—Geffray shows by an artificial head and spine and illustrations of cadavers of new-born infants that in determining the pressure of the cerebrospinal fluid the attitude of the subject should be taken into account. He also shows the importance of the attitude of the fetal spine in the birth process.

Transfusion of Blood.—Guillaume describes each of the various methods for transfusion of blood at present in vogue, and remarks that notwithstanding the progress realized in the last few years, there is still room for improvement. Not only the corpuscular elements in the blood but the volume of the blood fluid have to be restored to overcome the effect of severe hemorrhage. It is not necessary, he says, to restore as many corpuscles as have been lost, but enough should be infused to supply material from which new ones can be made, the presence of the corpuscles, in itself, acting to stimulate the production of new. He suggests that the blood to be used might be taken up in a syringe already containing a certain amount of physiologic saline solution. By this means the saline and the blood could be infused together, at one intervention supplying the two factors needed for the regeneration of blood: whole blood and sufficient fluid for the heart to pump on.

Intolerance of Certain Infants for Cow's Milk.—Marfan distinguishes between the children who merely do not thrive on cow's milk and those for whom it is an active poison. This latter group of cases is very small; the infants are usually from 5 months to 2 years old although instances have been known in children up to 6 years of age. He analyzes the arguments that have been presented to sustain the assumption that this intolerance for high grade milk is a form of anaphylaxis. He recalls, however, that to date no one as yet has determined in the blood of such children the presence of the proteins from cow's milk retaining their heterogenous character. The possibility of anaphylaxis from ingestion is still open to discussion; Bauer and Besredka's researches in this line were negative. The toxic manifestations may occur at the first ingestion of the cow's milk—a fact which does not harmonize with the conception of anaphylaxis. The toxic manifestations occur also irregularly and variably, and similar symptoms have exceptionally been observed with breast milk.

At the same time, the theory of anaphylaxis seems more plausible than any other yet advanced. A breast-fed child given cow's milk for the first time may at once present fever, vomiting, mucous diarrhea, sometimes bloody, with or without a rash, the respiration becoming fast and deep, with weak pulse, choleriform aspect of the face and tendency to collapse. This toxic clinical picture subsides at once on suppression of the cow's milk, but returns on its resumption. This clinical picture may develop suddenly in children who have been previously apparently thriving on cow's milk. Also in children who had been returned to the breast for a time, as they were not thriving on artificial food, and these toxic manifestations appear when they are given cow's milk anew. In a fourth group of cases, they develop when a bottle-fed baby has been kept on water alone for a day or two and the cow's milk is then resumed. Even a very small amount starts the toxic syndrome. Its sudden appearance even after as little as a teaspoonful of milk in the child's food, and the liability to return at each new ingestion of milk, are special features of this intolerance. In a case reported by Finkelstein, at the fifth attempt, the child getting 10 gm. of cow's milk diluted by a third, developed subacute enterocolitis immediately, with convulsions and death. The usual progressive aggravation at each repetition is one of the strongest arguments for the anaphylaxis theory.

Treatment may require saline infusion, camphorated oil and tepid baths, as for any choleriform diarrhea, in addition to stopping the cow's milk and feeding only water for a day and then giving breast milk or asses' milk. If the child is over 6 months old, gruels made with water, and sweetened, may be given. If breast milk is not available or the child is too young to be fed gruels, good results can generally be obtained by training the child to tolerance, that is, by giving 1 drop of milk in 50 gm. of water; an hour later 2 drops, and so on, every hour doubling the number of drops. When the child thus tolerates a teaspoonful every hour, stop the milk for twenty-four hours and then resume progressively, with longer intervals until the normal ration can be resumed. Water or vegetable broth can be given in addition, to supply the adequate nourishment. Whenever a child known to have displayed an intolerance for cow's milk returns to it after an interval of suspension, it should be resumed by this progressive technic. Modified milk is often borne better than plain milk; buttermilk or condensed or desiccated milk can be used first, to train to tolerance, returning later to ordinary milk. Schlossman has reported success in training to tolerance by injection of progressive doses of beef serum from 0.1 to 1 gm., but Salge's experience with this was disappointing.

The Cerebrospinal Fluid in Meningitis in Infants.—Crespin and Athias report a case of tuberculous meningitis and one of syphilitic meningitis, both in children under 2, breast fed, and both having urea in the lumbar puncture fluid. Urea in this fluid, therefore, cannot serve to differentiate meningitis of tuberculous origin as Nobécourt has recently asserted. It deserves the greatest attention, however, as possibly a sign of intoxication of some organ remote from the nervous system.

Hypertrophy of Right Heart in Infant.—The child of 9 months had inherited syphilis and, besides the *malformation* entailing the hypertrophy of the right heart, there was endocarditis of the mitral and tricuspid valves.

Lead Poisoning from Nursing Bottles.—Guerbet refers to bottles made from what is called crystal. He found that a child using one of these bottle was growing pale and developed eczema. The milk also showed slight discoloration. The glass is made with a certain percentage of lead.

Teaching of Therapeutics.—This is the inaugural lecture of Carnot's course on therapeutics which, he reiterates, is "the synthesis and the conclusion of all medical science. All our efforts to discover the causes of disease, its symptoms and lesions, have for their aim the cure of the sick. So that, for the therapeutist, scientific research is constantly supplemented by efforts for immediate practical results. This dual aspiration molding the mind of the physician makes of him at the same time a savant climbing to the peaks and a pitiably humble gleaner palpitating with humanity." Carnot includes in therapeutics all electric and other physical measures, climate and diet as well as vaccines, serums and organ extracts, besides all forms of psychotherapy.

Picric Acid Jaundice.—Merklen recalls that the discloration of the skin by picric acid and its derivatives occurs as a rule without any changes in the liver at first. Long kept up, however, the liver suffers and there is actual jaundice.

Action of Quinin on Stomach Functioning.—Baufle gave test meals to the same subjects with and without 1 gm. quinin sulphate or hydrochlorid in a cachet. The stomach content was examined in thirty minutes and again an hour later, the stomach being rinsed out each time with 200 c.c. of water. The effects observed demonstrate the necessity for selecting the preparation of quinin in accordance with the state of the subject's stomach. When there is a tendency to hypersecretion, the sulphate should be given the preference. With hyposecretion, the hydrochlorid should be selected as this stimulates sluggish glands to better secretion. It should be given from thirty to forty minutes before the meal, in about 100 or 150 c.c. of water. The quinin by this means will have passed out of the stomach before the meal begins, leaving the secretory glands stimulated to a high degree. The sulphate, on the other hand, modifies conditions very little, no more than the physiologic range.

Immunization by Inherited Syphilis.—The Mohammedans of Morocco are infected by syphilis to such an extent that scarcely 25 or 30 per cent. escape. In five schools at Fez, stigmata of inherited syphilis were found in 107 of the 272 children. In some of the others there is nothing to suggest syphilis except the positive Wassermann reaction. This warns of possible manifestations later, and calls for specific treatment of the children of syphilitics even when minor dystrophies may be the only sign of the latent disease. The evidence in regard to the fifth cusp among the children failed to confirm any connection with syphilis.

Medical Care of Repatriated Civilians.—Armand-Delille and Bernard describe the working of the service organized to care for civilians being sent back to France from the enemy countries. It comprises six separate services, including one for children, one for the tuberculous, and one for other diseases. A physician with two nurses boards the train as it crosses the border, and by the time it reaches the first stop the passengers are classified and those requiring emergency treatment are sent to the hospital. The vermin extermination service can attend to 200 per hour, and persons with parasitic affections are sent to an adjoining special hospital. In a recent eight months, 4,200 cases of scabies were given treatment and 234 cases of impetigo. Each case of tuberculosis is carefully classified and hospital or sanatorium treatment is provided. Those who refuse to go to such have to be allowed to proceed to where friends are awaiting them, but each is given a pamphlet of instructions and the family is given another pamphlet. A special notice is also sent to the prefect of the province so that the physician of the Comité départemental d'assistance aux anciens militaires tuberculeux can look after the case further. This complex medical service for the repatriated is in charge of fourteen physicians with large numbers of nurses: The whole system of care for the repatriated at the three receiving centers is admirably planned and organized. Valuable aid is constantly rendered by the American and French Red Cross and its London branch, the New Zealand committee, and French organizations, but above all, they say, "by the American Red Cross which here as elsewhere has given lavishly of its supplies and the devoted service of its personnel."

Rebellious Dyspepsia.—Nordman does not agree with those who think that the nervous element is the great obstacle in treatment of rebellious dyspepsia. His experience with large numbers of cases has always been that some organic thorn is always present in these intractable cases maintaining the irritation. There is usually a superposed neurosis, but back of all is the irritating organic disturbance thorn. The latter in a large proportion of cases is a colitis. In others, unsuspected amebiasis is responsible for the indigestion and weakness. Discovery of eosinophilia gave the first clue in one such case. In another case, there was no improvement under six months of sanatorium treatment for assumed tuberculosis, but after discovery of the ameba prompt recovery was realized under emetin and an arsenic preparation in small doses. In another group of cases the rebellious dyspepsia was the first manifestation of pulmonary tuberculosis. The dyspepsia improved under treatment, but the men soon returned with unmistakable pulmonary lesions. The number of such cases is legion, he says, and one cannot be too much on the alert to detect them. Taking the temperature regularly, tachycardia, modification of the pulse and low blood pressure may suggest incipient tuberculosis as the cause of what seems simple dyspepsia. He warns further that whenever there is recurring pain in the stomach in spite of repose and severe dietetic restrictions, ulcer should be suspected.

Amputation of Leg.—Phocas has the patient lie prone, face downward. He cuts the semicircular flap on the back of the leg, and ligates the vessels as he shows in illustrations. Then by merely lifting up the leg, flexing it at the knee, without disturbing the patient, he obtains free access to the other side of the leg. The exigencies of war surgery have often compelled him to operate on the patient in this prone position, and the theoretical objections against it were not realized in practice. Ether anesthesia proceeds smoothly, the lungs seeming to work unusually freely. It has even been his impression that postoperative vomiting was less frequent and the anesthesia more regular.

Present Status of the Wassermann Reaction.—Thibierge warns against undue reliance on the Wassermann reaction. Even competent and experienced biologists may obtain contradictory findings at times. It is not a chemical reaction but a test of the properties of certain substances of unknown composition, existing in unknown and certainly variable amounts, and the test is made by means of other substances of equally unknown nature present in the reagent also in unknown proportions, and associated in the reagent with a crowd of other substances, equally unknown and in proportions independent of those which are concerned in the reaction. Besides all these uncertainties is the personal equation, one observer regarding as positive what another would class as dubious or negative. Frequent control of the antigen is also indispensable to avoid misleading findings. He warns further of laboratories which play into fakers' hands, reporting the reaction as always positive. In dubious cases we should demand a test by known competent authorities before making the diagnosis or starting treatment for syphilis. In the first three weeks there is a reaction in about 68 per cent. of the cases; positive results even in as many as 91 per cent. of the cases cannot be anticipated before the seventh week. After the fifth week the Wassermann test is most dependable; before this only the discovery of the spirochete is decisive. During the war, mixed chancres have become comparatively common. The seroreaction six or seven weeks after the first symptoms will reveal whether the syphilitic infection is or is not associated with simple chancre. He declares further that the seroreaction is negative in about 10 per cent. of syphilitics with active manifestations of the disease. The reaction is liable to occur also in certain skin diseases in *nonsyphilitics*, and even in syphilitics with these skin diseases, who otherwise would respond negatively to the test. This fact has misled some into assuming a syphilitic origin for some of these skin and other affections, including Paget's osteitis deformans.

The Wassermann reaction should not be depended on as a guide for treatment during the first year of infection. The test should be applied occasionally as it may indicate whether or not treatment should be intensified, but it is folly indeed to give the patient to understand that continuing or suspending treatment depends exclusively on the Wassermann reaction as if it were an automatic therapeutic slot machine. In the latter stages of the disease, it is a useful guide when positive; it is less reliable when negative. Especially with syphilis of the nervous system, in which the Wassermann reaction is often negative, the patient would be deprived of the benefit from treatment if it were suspended because the Wassermann test was negative.

Thibierge insists that this test should not be allowed to modify the old rule that consent to marriage should not be given till four years from infection—some say six years—and when eighteen months have passed without manifestation of the disease. The only modification of this rule is that, after this delay, a positive Wassermann reaction calls for further postponement until it has veered to negative. He remarks that none of the authorities in syphilology have modified this rule for any patients who have presented manifestations of the second stage of syphilis.

In regard to energetic abortive treatment, he says that to date we have no means of positive knowledge whether the patient has been actually cured or not. Theoretically we may assume this, and sometimes we find that a patient has contracted a new syphilitic chancre. But in reality this occurs less frequently than we have been given to suppose, and it is more prudent to cling to the classic rules until longer experience has settled the question. The most that can be granted is that when the initial treatment was known to have been really energetic and repeated serum tests have been consistently negative, consent to the marriage might be given in three years. In conclusion he warns against breeding or fostering syphilophobia in impressionable subjects who ascribe exaggerated importance to the Wassermann test. The physician must be extremely careful in examining and in what he says in regard to the Wassermann test to easily unbalanced persons who have been exposed to syphilis. An imprudent word or the dictum of some irresponsible laboratory will convince nonsyphilitic men of this type that they have syphilis, and they then fall a prey to fakers of all kinds.

Grafts of Dead Tissue.—The success of Nageotte and Sencert in using dead tendons and other tissues to bridge gaps has been recently mentioned in The Journal. They here report experimental research which explains the mechanism of the process. The microscope shows that the ingrafted tendon blends with the living tissues until no line of demarcation can be detected. The dead graft actually comes to life, as it were. This occurs constantly with the proper technic with grafts the structure of which permits immigration of the connective tissue cells of its host. After the dead protoplasm has been carried off by the migrating cells, the fibroblasts flock into the persisting connective tissue frame left; circulation becomes reestablished and in time it is actually impossible to tell that the graft had been dead when it was implanted. Using grafts after fixation in alcohol or with formaldehyd, they do not induce any reaction and they become soldered directly to the tissues of the host without interposition of any new tissue. The eight illustrations give the findings in dogs; they show that there is no need to use fresh living grafts or living cold storage grafts, as the dead grafts of tendons, arteries, etc., answer the purpose perfectly.

Periodical Fever with Tibialgia.—Bourcart and Laugier describe what they think is a new clinical entity. The chills and fever resembled attacks of malaria except that the temperature never went above 39.5 C. (103 F.) and it took from thirty-six to forty-eight hours to reach this height and even longer to subside to normal. The intervals are of variable length. The febrile periods are accompanied by agonizing nocturnal pain in the tibias which become intensely sensitive, this tibialgia dominating the clinical picture. It appeared in small epidemics among troops in quarters previously occupied by Russians.

Hypocapacity of the Apex.—Breccia describes the physical signs which reveal that the apex is not expanding properly although otherwise normal. As this invites disease, he emphasizes the necessity for training the apex to do its work properly, advocating medical gymnastics, breathing exercises and other measures capable of promoting the expansion of the lung, especially in the young.

Ether Anesthesia by the Rectum.—Monod has applied this technic in thirty cases and the results were so fine that he commends it as a reliable method when conditions indicate this technic. He never had any accident or incident in his thirty cases while the security and tranquillity of the patient were most propitious for the operation. There were never any by-effects more than from any enema, while this technic seems to avoid the cardiopulmonary reflexes, the congestion of the lungs and the nausea. The ether was administered by a nurse, beforehand, like an ordinary enema.

*Glycemia in Diabetics and Renal Diabetes. R. Lépine.—p. 663.
*Response to Electric Stimulation of the Internal Ear. L. Bard.—p. 675.

*Early Teaching of Medicine at Strasbourg. R. Mourgue.—*p. 691.*
*Psychophysiopathic Syndromes. M. Dide.—*p. 697.*
*Parasitic Hemoptysis. M. Salomon and R. Neveu.—p. 707.
*Edema Fluids. E. Cottin and C. Saloz.—p. 720.
*Traumatic Epilepsy. R. Benon and G. Lerat.—*p.* 734.

Glycemia in Diabetics and Renal Diabetes.—Lépine declares that the generally accepted idea that the sugar *content* of the blood is abnormally high in diabetes is erroneous. It is based on determination of the sugar *content* only in grave cases, with complications. Many diabetics have less than 2 per thousand sugar in the blood, which is within normal range. Glycemia, consequently, is not necessarily an essential element of the clinical picture in diabetes. On the other hand, the permeability of the kidneys for sugar may become increased under different circumstances and the result is what we call renal diabetes. This seems to be of common occurrence in pregnant women. Experimental research indicates that nervous disturbances may be responsible for it or an upset in the endocrinous glands. He describes a number of instances of renal diabetes, without any signs of true diabetes, occurring in persons with chronic or long healed nephritis, or in the young in conditions like those with albuminuria of adolescence only that they presented glycosuria instead of the albuminuria. In two women inclined to hysteria, slight intermittent glycosuria alternated at times with albuminuria, depending on the diet. The glycosuria in one was always accompanied by polyuria. In other cases in apparently healthy persons, the glycosuria was only occasional and never very pronounced, while the sugar content of the blood was always below normal. An alimentary influencing of renal diabetes is nearly always unmistakable.

Deviation of the Head Under Electric Stimulation.—Bard reports the results of study of what he calls voltaic inclination, in normal subjects and with hemiplegia. Some of his previous conclusions on the sense of gyration were described in these columns, Nov. 23, 1918, p. 1780. He here describes some further laws he has worked out.

A Pioneer Medical Philosopher.—Mourgue cites from the works of Schützenberger, a Strasbourg professor of pathology in the last century, which prove that he was a pioneer in many fields of medical thought which are now common property. We forget those who blazed the way for the rest of us.

Psychophysiopathic Syndromes.—Dide refers to the contractures, etc., which have developed after a war wound in persons inclined to hysteria. A tendency to mental weakness and a shrinking from anything liable to induce pain are important factors, supplemented by a weakness in will power. All physicians who have anything to do with war wounds must repeatedly impress on themselves anew that joints grow stiff and useless when not used, and the will power and the brain grow stiff and useless unless inertia can be overcome. A phobia of pain, plus a condition of mental and motor weakness, favor the functional incapacity, and suggestion, created by habit, systematizes it. Secondary trophic or vasomotor disturbances then intervene to stabilize it.

Parasitic Hemoptysis.—Salomon and Neveu were impressed by the frequency of hemoptysis in troops and workmen from Indo-China and other Oriental countries, but they found that the hemoptysis did not mean the same in these men as is the rule elsewhere. Every bronchitis in an Asiatic that drags along and is accompanied by blood in the sputum, calls for hospital care and strict disinfection of the sputum, as it is liable to contain the eggs of the *Paragonimus westermanni* or *Distoma ringeri*. They insist that the discovery of distomatosis of the lungs is a warning to deport the patient if his condition permits sending him back to his home. These are the only means to prevent the development of foci of endemic distomatosis.

Edema Fluids.—When the edema is the result of kidney disease, the edema fluid shows the effects of dyscrasia—hence there is no reason for the fluid to be rich in proteic substances. When the edema results from heart disease, the fluid accumulates under mechanical influences only. It is the result of stasis, like the transudates, which have a higher albumin content than that of a fluid which is derived from a change in the composition of the blood. The study of the edema fluid thus reveals whether the kidneys or the heart are to be incriminated, and whether it is a question of compression or cachexia.

Traumatic Epilepsy Plus Hemiplegia.—Benon and Lerat report a case of epilepsy after a skull wound, with complicating delirium with hallucinations, transient mental confusion and functional hemiplegia. The case confirms what the war wounds are teaching more and more, namely, that the majority of cases of general epilepsy, such as used to be called essential epilepsy, all belong in the same category with the rest, namely, symptomatic epilepsy.

Treatment of *Influenza.* R. Massini.—p. 1633.
*Improved Technic for Vital Staining. B. Roman.—*p.* 1638.

Perforation of Tuberculous Mesenteric Glands.—*Iselin lists* among the conditions which may simulate acute appendicitis: perforation of stomach or bowel, gonococcus inflammatory lesions, tubal abortion and intra-abdominal menstruation, but devotes this article to perforation of tuberculous mesenteric glands. The resulting clinical picture deceptively simulated acute appendicitis in his eight cases of the latter. Four of the patients were children of 4 to 10 and the others were young women from 17 to 24. All recovered and one of the children was recently reexamined and found clinically normal. The amount of irritation of the peritoneum determines the symptoms. Even sterile pus, such as was found in one boy of 6, induces severe peritonitis. Softening and perforation can occur in mesenteric glands as well as in glands in the neck, and mixed infection is liable. It is perhaps surprising that tuberculous mesenteric glands do not suppurate and perforate oftener. Roentgen exposures promote and hasten the softening of tuberculous glands, hence suppurating mesenteric glands should not be exposed to them. Hyperplastic glands benefit by the exposures, but the danger of perforation is imminent when suppurating glands are exposed. He had one case in which roentgen treatment of tuberculous peritonitis was followed by a tuberculous ulceration in the bowel rupturing into the open abdomen. There is a possibility that tuberculous peritonitis starts with perforation of a softened gland. The way in which the nodules are usually distributed seems to sustain this assumption. The similarity of the clinical picture with perforation of a gland and with acute appendicitis is an advantage as it brings prompt operative intervention.

Meckel's Diverticulum in Hernia.—The inguinal hernia developed through the cicatricial tissue from two former hernia operations, and Meckel's diverticulum projected from the lowest point of the large hernia. It was gangrenous from incarceration in the opening in the skin. The patient was a man of 79 and the rupture had occurred suddenly while he was pitching hay.

Vital Staining of Elastic Fibers.—Roman describes research with a substance which stains a rabbit violet although outside of the animal it does not look nor behave like a stain. It is a modification of atophan, thienyl-chinolin-carbonic acid, and seems to affect chiefly the elastic fibers, especially those of the vessels. A violet stain can be isolated from the urine of the animals. Fifteen pages are devoted to analysis of the findings with this vital staining and comparison with them of similar research by others.

The Cerebrospinal Fluid with General Paralysis and Syphilis of the Nervous System. *G. Sabatini.*—p. 1230.

Pseudopleuritic Pneumonia.—De Sandro reviews the present status of what he calls *splenopolmoniti,* and tabulates the findings as compared with those with true pleurisy with effusion. With the former, the left lung is predominantly affected, and the subjects are usually males. The onset is sudden and the course takes from three to seven weeks; the disease only gradually reaches its height and as gradually subsides. The fever is higher and the pain more intense than with true pleurisy. The patient lies on either side, while with true pleurisy he lies on the side affected. The dulness does not change its position.

Spirochete Bronchitis.—This disease to which Castellani called attention in 1904 has been encountered since in both the old and the new world. It may appear in an acute form as a simple bronchitis with fever and bloody sputum or it may assume a chronic form, but the general condition is not much impaired as a rule. Violle has encountered cases in which the bronchial secretion reached a liter a day. Spirochetes abound in the sputum. Castellani has suggested tartar emetic in treatment but symptomatic measures alone are the general reliance.

Thyroid Abscess.—In the case described the abscess in the thyroid was a metastasis from pyemic otitis and *mastoiditis,* but there was no thrombosis in the transverse sinus. A *few* days after the first symptoms of the thyroiditis a clinical picture developed suggesting certain features of exophthalmic goiter, but these all gradually subsided after the abscess had been cleared out. The streptococcus was cultivated from both the thyroid and the mastoid pus.

True Neuro-Arthropathies.—Aievoli's patient is a man of 58 with tabes and hydrarthroses of both knees. He ascribes it to the hypotony due to the tabes, analyzing similar cases described by others.

Determination of Sulphates and Phosphates in the Urine.—The method of research described is based on the fact that in urine treated with magnesia *usta* all the phosphoric acid is precipitated, while the filtrate contains the sulphuric acid which can then be estimated by a color reaction with hydrochloric acid, as is described in detail.

Acute Meningitis.—Costantini reports some recent cases of epidemic meningitis in which the cerebrospinal fluid seemed to be free from bacteria, but contained numbers of large mononuclear cells.

*Tracheobronchial Glandular Disease. E. Podestà.—p. 561.
*Unilateral Horse-Shoe Kidney. A. F. Canelli.—p. 577.
*Salt Fever in Infants. A. Spallicci.—p. 583.

Symptoms with Tracheobronchial Disease in Children.—Podestà remarks that there are no pathognomonic symptoms early in tracheobronchial glandular disease in children, but when a child fights against being examined, its *manner of* breathing is instructive. Disease in these glands is frequently overlooked in docile children who submit calmly to examination. The child should be disrobed; this may reveal tuberculids or an eruption throwing light on the differential diagnosis. It may also reveal enlarged and congested veins at some point, suggesting pressure on the veins from an enlarged gland. Any tendency to varicose veins or edema is instructive, as also any tendency to dyspnea, or breathing suggesting asthma. The expansion of the chest on this side *may* not equal that on the sound side. A tendency to asymmetry can be detected more often than the textbooks admit. As an infant cries or screams, the middle portion of the supraclavicular regions may protrude. This is still more evident when the child holds its breath as it fights those examining it, but it is most pronounced when the child coughs, especially when the coughing is spasmodic as often occurs with diseased tracheobronchial glands. This supraclavicular *protrusion* is usually transient, occurring only during the phase of *expiration,* and especially when this is forcible, as during a spasm of coughing, or when the child tries to sit up in bed *while* an adult prevents this by putting his hand on the child's head. *There is* no protrusion when the child is tranquil, or during *inspiration.* The protrusion is usually but not always bilateral, and the most pronounced protrusion may be on the side *in which the* glands most closely approximate normal. The apex of the lung seems to be responsible for this bulging of the region over *it.* There is probably more or less emphysema in the apex and superior lobe *in general,* and an increase in the intrathoracic pressure, owing to the *enlarged glands, and* these are manifested by this bulging. In one case *the* necropsy findings confirmed the assumptions based on this transient protrusion of the chest wall. Before accepting it as a sign of tracheobronchial adenopathy, all other affections *liable to* induce emphysema have to be excluded. Its appearance only on one side is significant, as the glands involved are usually those linked on one side, and mostly on the side of the lung focus, if there is one.

Horse-Shoe Kidney on One Side.—The anomaly was a postmortem surprise. The *young* soldier had succumbed *to* a war wound of the liver and the *single kidney* was found 15.5 cm. long by 9 cm. wide. It was turned back on itself so that this elongated unilateral kidney presented the outline of a horse shoe. There was *some malformation* also of the vena cava.

Salt Fever in Infants.—Spallicci reviews *the literature* on this subject and gives the findings in a number of infants. Everything testifies to the fact that there is no febrile reaction to subcutaneous injection of 40 or even 60 c.c. *of* 0.85 per cent. saline when *it has been* thoroughly sterilized for at least an hour in the *autoclave. On the other hand,* even 20 c.c. will send up *the* temperature when the *saline has* not been sterilized properly.

Peruvian Verruga.—Hercelles describes the important part played by the spleen in this disease, from the first stimulation to exaggerated functioning as a *defensive* reaction, with intense phagocytosis, *then* aiding in repairing the injury to the blood, and finally *returning* to the rôle of the fetal spleen, such as *Dominici* has described. Several fine colored plates show the different phases of *this* intense functioning on the part of the spleen, the necessary congestion as also the complications of a septicemic nature. With the former, fibrous transformation finally ensues; with the latter, infarcts develop. The spleen thus plays the leading part among the organs in this disease. Arce describes the clinical course, pathology and treatment of the malignant form of Carrion's disease. He advocates intravenous injections of neo-arsphenamin, every four or five days, in doses not over 0.2 or 0.3 gm. to a total of three or four doses. The patient's strength should be kept up with a light liquid or semiliquid diet, and epinephrin, camphorated oil, etc., should be given as needed, but purgatives, diaphoretics and antipyretics should be absolutely avoided. *In no disease is this latter rule more important than* in Peruvian verruga in its malignant form.

Some Technical Points in Histology. E. P. Lasnier.—p. 512.

The Paraglandular Organs.—De Castro applies this term to the formations which accompany the endocrinous glands in the human body. They are of the same embryonic origin, and attain a certain degree of differentiation in their development, but they are generally regarded and classed as supernumerary accessory glands or aberrant glandular nodules. He is convinced that they represent a regular system, and are not merely anatomic curiosities, morphologic accidents, anomalies or rudimentary organs, as they have hitherto been described. They form what he calls the paraglandular system, an annex to the system of the glands of internal secretion. They represent an organic system in full evolution. This allows the interpretation of a number of contradictory facts which have hitherto baffled observers, and explains many phenomena in the human economy. Each of the endocrinous glands is liable to have its paragland, as also possibly the epiphyses. There are also abdominal paraganglia, such as the organs of Zuckerkandl and the cardiac paraganglia described in 1906 by Wiesel and Wiesner. The carotid gland is not exceptional but occurs bilateral in nearly every one. Other paraganglia with chromaffine tissue are found along the sympathetic. Luschka's coccygeal gland is not chromaffine and hence does not belong to the paraglandular system. He reviews each member of the system in turn, with evidence from comparative anatomy and physiology to sustain his views.

Acute Gastritis with Cholecystitis.—Navarro reports four cases in which severe gastritis developed suddenly, resembling the toxic gastritis under chloroform. As the patients vomited they felt a vague and diffuse pain in the region of the epigastrium but the complaints were mainly of a smarting in esophagus and throat, almost as if the vomit were burning the tissues. The patients were all adults, and the evidences of serious toxic action were soon apparent as the strength rapidly declined. The rapid pulse and cold extremities in one case suggested rupture of a tubal pregnancy, as the menses had been suppressed for two months and there was right salpingitis. The temperature was not high in any case and the clinical picture soon improved in one case but in the others it was alarming. In one patient the gastritis recurred. In three cases there was a history that suggested gallstone disease in the past, and the operation confirmed that cholecystitis was responsible for the secondary toxic gastritis. This was beyond question also in the other case, but the age (83) precluded an operation. The severe gastritis in each case was conquered by rinsing out the stomach, with ice to the epigastrium. Soon all pain in the stomach and other disturbances subsided but this left the dull ache in the gallbladder. Cholecystitis is thus able alone to set up a severe toxic gastritis, but the cholecystitis itself may be secondary to an old appendicitis or to puerperal infection. Navarro queries whether the gastritis in these cases is due to exceptional toxicity of the contents of the gallbladder or to nervous influences. Two of the cases reported were in brothers.

Cholesterol Content of the Blood in Health and Disease.—Posse discusses the biologic rôle of cholesterol in physiologic and pathologic conditions. It seems evident that the presence of toxic substances in the blood entails abnormally high arterial blood pressure, with cholesterolemia as a defensive reaction. Colesterol is not readily soluble and consequently precipitates form from it. These precipitates infiltrate the walls of the vessels at certain points, producing permanent changes in them, modifying the lumen and the elasticity of the vessel walls. Certain states favor this precipitation and others oppose it; thus Lemoine has noted that arteriosclerosis is comparatively rare in the obese. He ascribes this to the solubility of cholesterol in fats. Inversely, Remlinger suggests that retention of semen, so rich in cholesterol, would tend to favor development of arteriosclerosis. The therapeutic conclusion is evident that the introduction or retention of toxic substances in the organism stimulates to hypercholesterolemia and hence to arteriosclerosis. Lemoine consequently repudiates iodids and nitrites in treatment as aggravating the condition one is seeking to remedy. In chronic nephritis and in cholelithiasis, factors raising the cholesterol content of the blood increase the tendency to production of concretions. This tendency should be warded off, Navarro explains, by the diet, keeping the intake low of fats and other substances liable to augment the cholesterolemia. This should be borne in mind in chronic kidney and gallstone disease, in gout and in the pregnant. Chauffard has reported the case of a woman with mild tuberculosis put on a diet of eleven eggs a day, and in three months there was an attack of gallstone colic with jaundice. On the other hand, it may be advisable to increase the cholesterol content of the blood as an aid in combating toxi-infections. Cholesterol itself could be given, an ethereal extract by the mouth, along with foods rich in cholesterol, including butter. Production of cholesterol might also be stimulated by suprarenal and corpus luteum treatment. The conditions in which cholesterolemia has been intentionally promoted, as a therapeutic measure, to date are pernicious anemia, exophthalmic goiter, certain forms of tuberculosis with hypocholesterolemia, and in the acute period of infectious diseases.

Pathologic Anatomy of the Spleen. O. Hercelles.—p. 272. Cont'n.

Cirrhosis of the Liver.—Odriozola reports the case of a man of 34 with alcoholic cirrhosis of the liver and ascites. At the first tapping over 11 liters of ascitic fluid were withdrawn. As the liver and spleen were much enlarged, the prospects for a cure were better than with the atrophic type of cirrhosis. In these cases the ascitic fluid has to be withdrawn often, without waiting for large amounts to accumulate. An indispensable element in the cure is abstention from alcohol and likewise the staying in bed as long as the tendency to ascites persists. Odriozola regards this as of vital importance. Being up and about is painful and prolongs the disease. It is thus possible to watch over the patient better and supervise his diet. The diet was selected to avoid purins, milk at first, with, later, starch dishes and cooked vegetables. The bowels are kept open with mild laxatives, and organic iodin preparations are given in small doses. Under these measures the man in the case reported was discharged in good condition in three months.

Echinococcus Disease of the Lungs.—Corvetto describes two new cases which confirm that there are no pathognomonic symptoms of an echinococcus cyst in the lung, aside from discovery of the parasite in the sputum, but the roentgen rays may give the clue, locating the cyst and facilitating operative measures. He has encountered four cases of the kind and knows of two more at Lima, so the pulmonary form is not so rare as generally assumed. In one of the cases the symptoms and course simulated pulmonary tuberculosis until expulsion of the cyst membrane cleared up the diagnosis and put an end to the disease at one stroke. Hemoptysis with a tenacious cough and other pulmonary symptoms should not be labeled tuberculosis as a matter of course.

Ambard's Ureosecretory Constant.—Flegel, Iturbe and Gonzalez extol the combination of the various measures in vogue for estimating potential renal functioning. The combination of different methods of exploration of the kidneys gives almost positively reliable information, as when nephrectomy is contemplated. The six methods of investigation described are the dilution test, the phlorizin test, chromoureteroscopy, the phenolsulphonephthalein test, the Ambard formula, and the application of the laws regulating the urea and the chlorids in the segregated urine.

Early Diagnosis of Extra-Uterine Pregnancy.—Bengoa remarks that the condition of the breasts aids in early diagnosis of an ectopic pregnancy except when less than eighteen months have elapsed since a preceding pregnancy. The gravid tube is movable, and he has always found it more or less in its normal place. It is seldom enlarged to the size of two fingerbreadths, and it is not tender. Pain in the stomach, a little vomiting and transient fever may have been the only manifestations of an attack of appendicitis which has left an exudate fusing the organs together, including the tube or ovary or both. But this is seldom mistaken for a tubal pregnancy.

Dyspepsia of Cardiac Origin.—Goyena analyzes a typical case in which failing compensation of a valvular lesion was accompanied by a set of symptoms on the part of the stomach, overshadowing the heart disease and long treated for dyspepsia only. In such cases the symptoms are vague and diffuse, oppression and distention in the stomach region, a dull ache, with occasional vomiting. There is always retention of chlorids, even without edema, the chlorid content of the blood being always above normal. Hematemesis is an important symptom, or there may be merely occult blood in the stools or vomit. All these manifestations on the part of the stomach are the result of defective circulation from insufficiency of the myocardium. It is felt also in the liver, the stools showing the insufficiency of the liver. The diagnosis of the cardiac origin of the gastric disturbances is confirmed by the striking effect of treatment directed to the heart alone. The first thing is to reduce the work of the heart. This he accomplishes with a purgative; one like sodium sulphate which is not readily absorbed but acts at the same time on the liver. The patient should be kept on milk alone for a time. This not only facilitates digestion but has a diuretic action. This reduces the minimal tension, while the maximal tension is raised by giving some heart tonic, digitalis or strophanthus. The subsidence in two or three days of all the symptoms of dyspepsia confirms the cardiac origin. "The patient," he says, "enters the physician's office a *gastrico* and leaves it a *cardiaco*, with all that that implies."

Tuberculin Treatment.—Wimmer gives the details of twenty cases of different forms of tuberculosis to illustrate the excellent results that can almost be counted on with tuberculin treatment as an adjuvant to the usual measures. The mode of reaction in each patient should be carefully studied and the tuberculin gaged accordingly. The greater the reaction, the more cautious should be the dosage of the tuberculin. The most promising cases are those in which there is an intense reaction but without modification of the pulse, in which the congestion and the fever yield to small doses, and the weight shows a very slow but progressive increase.

Referendum on Influenza. A. P. Fernandez and others.—p. 834.

What the Hospital Should Be.—Rodriguez protests against building hospitals with marble halls, etc., to defy the centuries. They should not be expected to last very long, only long enough to serve for the care of the sick with the means available during the epoch in which they are living.

Surgical Sequels of Influenza.—Iñigo remarks that almost the only sequels of influenza which require surgical intervention are pleural effusions. In the effusions examined at Madrid, a streptococcus was found in large numbers, in pure culture. For this and other reasons he made a point of puncturing and draining at once on suspicion of a pleural effusion, purulent or not, and the results were surprisingly gratifying, as he relates in detail.

Sugar in Treatment of Tuberculosis.—Pittaluga describes the theoretic and experimental bases for intramuscular injections of saccharose in treatment of pulmonary tuberculosis, and reports the case of a young woman with pronounced pulmonary lesions, living in unhygienic surroundings, whose condition was favorably transformed by a series of injections of 10 c.c. Reduction of the local manifestations and a certain degree of euphoria were thus realized by this measure. It seems destined to prove a useful adjuvant to the usual means of treating the tuberculous. More than this should not be expected of it. (See *page* 313.)

*Miostagmin Reaction *with* Chicken Sarcoma. K. Tadenuma.—p. 38.
*Malignant Transformation of Fibroma in Mesentery. I. Miwa.—p. 39.

Malignant Transformation of Transplanted Benign Tumor.—Umehara reports that he has succeeded in cultivating a transplantable sarcoma from a benign adenofibroma. The spontaneous benign tumor, about as large as a walnut, was found on the breast of a white rat. In structure it closely resembled human adenofibroma and scraps and emulsions from it were injected in 423 rats, with the development of a large tumor in 144 of the animals. By this means he was able to study the conditions of evolution and growth of the neoplasm through entire generations. In different series of experiments he studied the effect of mechanical, thermic and chemical influences on the transplants. In this instalment of his report he says that he has carried the research to the fourteenth generation. In the early generations about 90 per cent. of the transplants gave positive results, while this has declined to 15 per cent. in the later generations. He refers to the transformation to sarcoma only in the heading to his article, which is to be continued.

Miostagmin Reaction with Hen Sarcoma.—Tadenuma states that the miostagmin reaction was seldom positive before the twentieth day after the tumor-grafting operation. Later than this it was almost invariably positive, but veered to negative again after extirpation of the tumor.

Malignant Transformation of a Fibroma in the Mesentery.—The man of 56 had long had a movable tumor in the left side, about as large as a goose egg. It suddenly began to enlarge and proved fatal in less than two years. It proved to be a fibroma in the root of the mesentery which had undergone malignant degeneration with extensive metastasis. The illustrations show that the tumor had developed a fibrosarcoma and also a *myxofibroma*.

Case of Quincke's Edema with Irritation of Vagus. Koster.—p. 1485.

Dextrocardia.—Indeman reviews what has been published on congenital dextrocardia or situs cordis inversus, and reports a case in a young man and in the young man's mother's brother. This is the first case of familial dextrocardia on record, he believes.

Visual Phenomenon Through the Lid.—Wassenaar calls attention to the flash of bright red light which one sees when one eye is entirely covered and the other eye is alternately rapidly covered and then exposed to a moderate light, the eyelid closed. He theorizes that the visual apparatus reacts to a stimulus at the first beginning differently from the way it reacts a moment or two later.

Utilization of Protein in the Food.—Van Leersum tabulates the results of research which explain the conflicting findings of different investigators with coarse bread, as they demonstrate that the absorption of nitrogen depends on the length of time the food remains in the bowel. Persons with lively peristalsis pass it on so quickly that all the nitrogen does not get digested and assimilated, while others with a tendency to constipation get a chance to utilize it to the last particle.

Hypertrophy of the Prostate.—Mieremet presents a number of arguments to sustain the assumption that the hypertrophy of the prostate is due primarily to the action of a hormone from the testicles. If the hypertrophy were merely a tumor, then we might expect it to occur at any age, while in fact it affects almost exclusively men at a certain age. The phenomena observed with roentgen exposures of testicles and prostate also sustain his assumption. He thinks that not enough attention has been paid to the internal secretion of the testicles as a factor in enlargement of the prostate, and urges research on the testicles in cases of hypertrophied prostate.

*Experiences with Surgery of the Ureters. G. Nyström.—p. 109.
*New Urethra Formed from Saphenous Vein. C. Adlercreutz.—p. 163.

Ureter Surgery.—The surgical section of the *Nordiskt Medicinskt Arkiv* has a name for itself now, the *Arkiv för Kirurgi*, and the articles in it are published in the language the writer prefers; Nyström's article is in German. He describes a large number of unusual operations on the ureters; one for stenosis from appendicitis. In one case he bridged a gap in the ureter with a plastic operation, utilizing a strip from the abdominal wall.

Plastic Operation for Hypospadia.—The man of 58 with complete hypospadia was operated on at one sitting; the new urethra being made from a segment cut from the internal saphenous vein. The man had been brought up as a girl to the age of 23, and had been twice married, but had no children. The graft of the vein proved finally successful after several mishaps, including stenosis requiring excision of the stricture. Cystitis developed and epididymitis, and a calculus had to be removed from the urethra. It had formed around a scrap that had broken off from the retention catheter. Internal urethrotomy was also required. The vein proved to be smaller than had been anticipated, but the final urethrotomy remedied this. Adlercreutz compares with this the other methods of treating complete hypospadia. Unless the new tube is made wide enough, the patient will never be freed from his perineal fistula or it breaks out anew if it heals, whatever the method employed. A tube should be provided as wide as the patient's posterior urethra, that is, allowing the passage of a No. 23 or 24 Charrière. This patient still keeps up the dilatation with a catheter of this size a few times during the week, and his condition is highly satisfactory.

*Perforated Gastric and Duodenal Ulcers. H. Hertz.—p. 1801.

Perforated Gastric and Duodenal Ulcer.—Hertz devotes twenty pages to the tabulated details and outcome in 60 cases of perforated gastric or duodenal ulcer in the last few years at the public hospital at Copenhagen. The age of the patients ranged from 16 to 75; only 17 were women. In two fifths of the 13 duodenal ulcer patients no preceding symptoms had been noted before the perforation. The absence of dulness over the liver is an important symptom of the presence of air in the abdominal cavity, but in 12 of the cases the liver dulness was practically unmodified. In about 50 per cent. of the cases transient vomiting occurred at the time of the perforation. Two patients presented two perforations and in several cases necropsy showed other ulcers besides the one that had perforated. Petren has reported several ulcers present in 27 per cent. of his cases. The amount of fluid escaping into the abdominal cavity seems to be comparatively immaterial; some of the patients with the larger amounts recovered. In 12 of the patients the peritoneal contents developed cultures, in all but one of the staphylococcus; 7 of these patients died. At necropsy in all the fatal cases the suture of the perforation had held perfectly; death was due to complications elsewhere. No attempt was made to excise the ulcer in any case. Petren and Rovsing advocate excision, and have reported the recovery of all in their later series of 12 duodenal ulcer perforation cases, including 3 with a chronic fistula and no acute perforation. In only 17 of Hertz' 60 cases was the diagnosis correct when the patient was sent to the hospital; appendicitis was the usual assumption. The outcome of operative treatment was recovery in 75 per cent. of the 19 with a delay of six hours or less; 66 per cent. recoveries among the 12 with interval of from six to twelve hours after the perforation, while only 20 per cent. recovered of the 22 with a longer interval than this. The total mortality was thus 27 out of 53 operative cases, over 50 per cent. He adds that the temperature is not of moment, but a pulse under 90 or 100 is a favorable sign as also a sterile peritoneal fluid, and good general condition; all the patients with signs of collapse died, as also all those with distended abdomen. The operation should be done with the least possible delay and the field of operation should be walled off from the rest of the peritoneal cavity. The peritoneum should not be rinsed except in the cases seen late; and the same rule applies to drainage. Simple suture of the ulcer seems to be preferable to excision or gastro-enterostomy.

THROMBOSIS OF THE CORONARY ARTERIES

JAMES B. HERRICK, M.D.
CHICAGO

In a paper[1] on certain clinical features of sudden obstruction of the coronary arteries, read six years ago before the Association of American Physicians, I called attention to the fact that while such obstruction as by a thrombus was very often suddenly fatal, it was not necessarily so; for the coronary arteries were not in the strictest sense terminal arteries; there were often anastomoses capable of reestablishing circulation in the infarcted area to such an extent as to enable the heart to functionate for a time at least. This had been shown by anatomic study of the coronaries, by necropsy observations by the pathologists, by experimental ligation of these vessels, and by clinical experience controlled by postmortem examinations.

A tentative grouping of the cases of coronary thrombosis based on clinical symptoms was made:

1. Cases of instantaneous death, a group graphically described by Krehl, in which there is no death struggle, the heart beat and breathing stopping at once.
2. Cases of death within a few minutes or a few hours after the obstruction. These are the cases that are found dead or clearly in the death agony by the physician who is hastily summoned.
3. Cases of severity in which, however, death is delayed for several hours, days or months, or recovery occurs.
4. A group that may be assumed to exist embracing cases with mild symptoms, for example, a slight precordial pain ordinarily not recognized, due to obstruction in the smallest branches of the arteries.

It was Group 3 whose clinical phenomena were discussed, as illustrative of which a few cases were briefly cited, including one with necropsy findings.

These cases of coronary thrombosis are, as it seems to me, of commoner occurrence than is generally supposed, and that is the justification for repeating some of what was contained in the former paper and for adding reports of other cases and for touching on some recent experimental work that has a direct bearing on this subject.

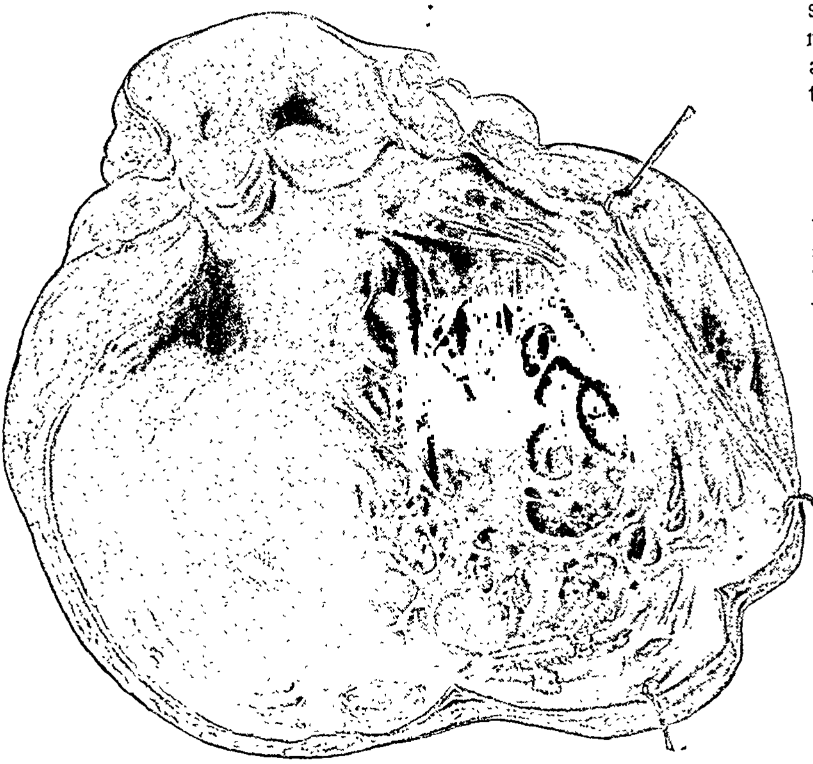

Fig. 1 (Case 3).—Changes on the endocardial surface of left ventricle.

CLINICAL SYMPTOMS

Most of the patients are middle-aged or elderly men. The heart and blood vessels in many show the evidence of arterial and cardiac sclerosis; the blood pressure may be high. In others no sign of such change is to be made out. In fact, in two of my three cases with necropsy, the only significant vascular sclerosis was in the coronary arteries, the hearts were of normal size, and there had been no hypertension during life. In one there was slight involvement of the beginning of the aorta. Previous attacks of angina pectoris may have been experienced. If this has been the case, the patient will describe the attack due to the coronary thrombosis as of unusual severity. Often there is no assignable cause for the attack such as is commonly noted in the typical paroxysmal angina—walking, a heavy meal, undue excitement, etc.—though in some cases these exciting factors seem to provoke the attack or, at least, greatly to aggravate it when it has started. The painful seizure is usually more enduring than in ordinary angina, the spell lasting many minutes or several hours, or a status anginosus developing. The location of the pain, as in the classical angina, is commonly substernal, with frequent radiation to the arms and neck. But in many of the thrombotic cases the pain is beneath the lower sternum or even in the upper epigastric region; and there may be no radiation to the arm or neck. This epigastric reference of the pain, with the nausea and vomiting that freqeuntly occur, often suggests to patient and physician some abdominal accident, such as acute pancreatitis perforation of the gallbladder, or a gastric or duodenal ulcer. And these suspicions are strengthened by the fact that there are so frequently signs of shock and collapse—ashy hue of the face, clammy skin, and small, rapid, feeble pulse.

---

[1] Herrick, J. B.: Clinical Features of Sudden Obstruction of the Coronary Arteries, J. A. M. A. 59: 2015 (Dec. 7) 1912.

The heart is commonly rapid, even to 140 or more, though slow heart action has been recorded. There may be irregularities, such as extrasystoles or partial block. The pulse usually lacks in strength and may be almost imperceptible, though in some cases the strength is wonderfully well preserved. Blood pressure is lowered, and tends to grow lower in the unfavorable cases. The heart tone may be startlingly faint, both because of the weakness of the heart's musculature and because of an acute emphysema that may develop and mask the heart sounds. Over the infarcted area a pericardial friction is sometimes heard. The heart may reveal evidence of dilatation by its increased area of dulness and its mitral systolic murmur due to relative insufficiency of the valve. Râles in the bronchi, with other evidence of pulmonary edema, may be present. Passive congestion of the kidney may show in a trace of albumin in the urine. In some cases, cardiac edema of marked degree appears, the albumin being large in amount, the legs badly swollen, and free fluid being present in the abdominal cavity. The mind is commonly quite clear. I have been surprised at the preservation of bodily strength that is often manifested. Patients occasionally walk about within a few hours after such a seizure, and within a few days may be outdoors trying to attend to business.

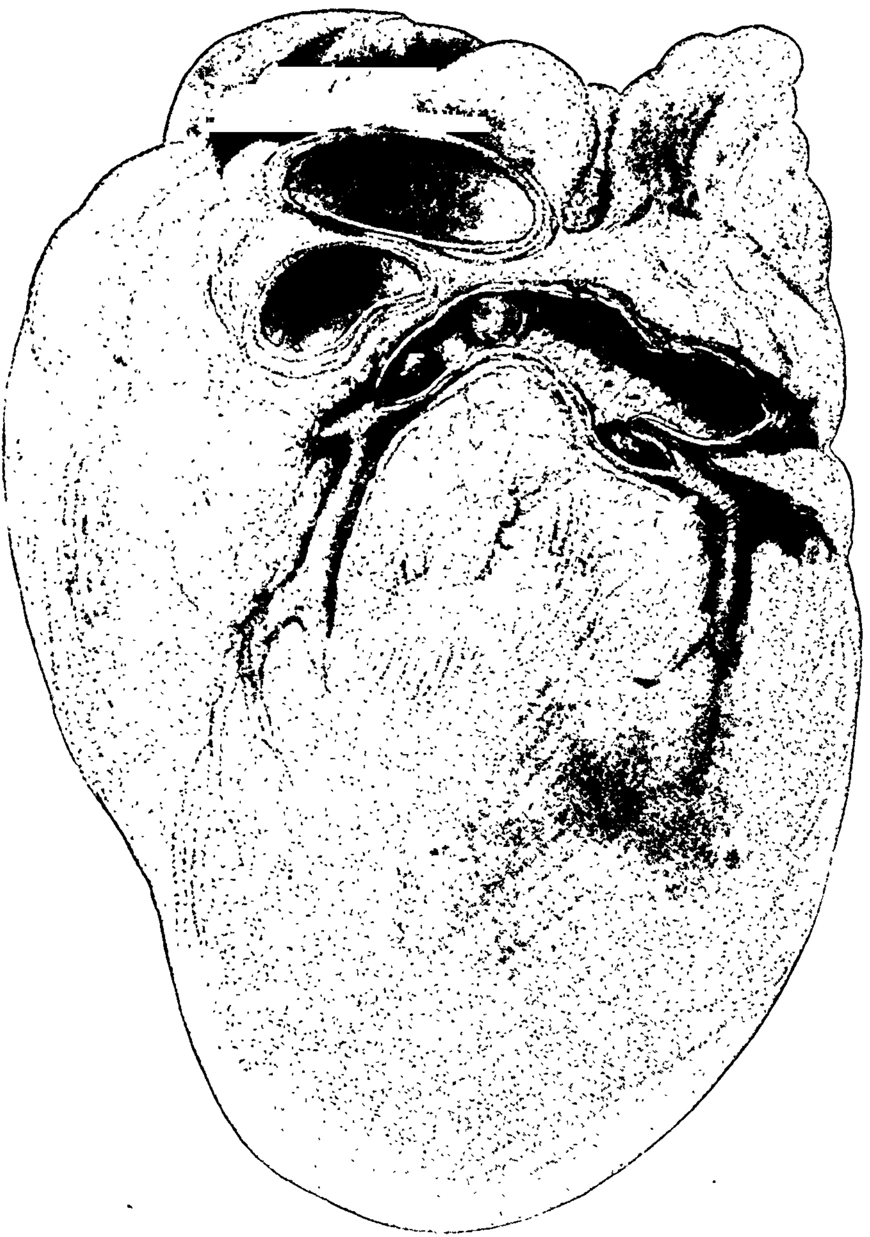

Fig. 2 (Case 3).—Site of thrombi and fairly normal external appearance of heart.

These symptoms will often enable one to make a reasonably certain diagnosis of acute obstruction of the coronary artery. As in so many other conditions, the first essential is to think of this condition as a possibility and to rid the mind of the notion that such a diagnosis is possible only at necropsy.

In the following three cases the diagnosis was confirmed by necropsy. In the first instance, the first I had ever recognized clinically, the diagnosis was decidedly tentative nad hesitating. In the other two, as well as in several in which no necropsy has been permitted or in which the patients are still living, diagnosis has seemed definite, as clear, for instance, as in most cases of obstruction of a cerebral vessel. I give very brief abstracts: Case 1 is reported more in detail in the article of six years ago.

REPORT OF CASES

Case 1.—A man, aged 55, was seized with severe pain low in the chest and epigastrium. He vomited. The physician, believing, as did the patient, that the attack was of gastric origin, washed out the stomach; but relief came only with morphin. The man lived fifty-two hours. He was conscious to the last. His pulse from the first was rapid and very weak, the heart tones nearly inaudible. An acute emphysema with many moist râles developed. No abdominal or other than cardiac cause could be made out as an explanation of the condition. The temperature never was above 99.2 F. The left ramus descendens was found plugged by a thrombus at a narrow spot where there was a small pathologic mural roughening and thickening.

Case 2.—A man, aged 62, while walking on the board walk at Atlantic City, was seized with a terribly severe pain in the lower precordia. He was helped to the hotel, but refused to call a physician while in Atlantic City or for the next two days while in New York, for, as he said, he knew from the severity of the initial pain, the great weakness and difficult breathing, that he would be ordered to a hospital, and he wished to get to his home in Chicago for his illness and, as he feared, his death. He lived over two weeks from the onset of the attack. His heart when he reached Chicago was dilated, weak and somewhat rapid. His blood pressure became progressively lower. There were dyspnea, cyanosis and marked edema of the legs and albuminuria. Death was as in ordinary cardiac failure. Necropsy revealed recent plugging by a thrombus of the descending branch of the left coronary, with softening of the heart muscle at the left apex and the lower interventricular septum.

In this, as in the other case cited, the aorta was free from evidence of sclerotic change. No other vascular lesions were found than the isolated patches of sclerosis in the coronary. It happened also that in each case the patient had only a short time before been carefully examined by competent physicians and had been pronounced in good health as to heart, blood pressure, urine, etc.

Case 3.—A physician, aged 42, who had never suffered from angina pectoris, had no acute or chronic infection so far as he knew, and who regarded himself as free from cardiovascular and renal disease, was seized, while in this seemingly good health, with a sudden, excruciating pain in the lower sternal region, which pain radiated to the arms and to the epigastrium. He was profoundly shocked, very weak and nauseated, the skin cold and clammy, the pulse rapid and thready. His colleagues who saw him thought he would die in a very short time. Morphin was necessary to control the pain. After a time he rallied, and in ten days was able to be about and even tried to do some professional work. But in a few days his weakness, precordial distress on exertion, dyspnea and irregular, rapid and small pulse caused him to give up. He rested, again improved, and came to Chicago. He was seen by my assistants, J. R. Greer and F. M. Smith, who ventured a diagnosis of coronary obstruction, a diagnosis that I felt was correct when I saw him a few days later. Electrocardiograms taken on these two occasions gave support to these opinions, a point to which reference will be made later. Rest and small doses of digitalis were ordered, and improvement followed. The summer vacation was spent on an island, where there was considerable violation of the injunction as to quiet and digitalis, the patient not only eating very heartily, but not infrequently going on strenuous walks, fishing and hunting trips, even though precordial pain, occasional attacks of dyspnea, and cardiac irregularity gave warning that the heart was far from normal. From an unduly severe strain of this sort he suffered for several days with dyspnea and arrhythmia; he contracted an infectious bronchitis and hastened to Chicago, where, in a deplorable condition, he went under my care in the Presbyterian Hospital, Sept. 26, 1917. The dyspnea and cyanosis were marked; he was sleepless and had Cheyne-Stokes breathing; the temperature rose to 102. The blood pressure was not high, the heart was slightly enlarged to the left, and there was a faint systolic murmur at the apex. After four days he developed signs of pneumonia; the respiration rose to 32 and the temperature to 105; there were bloody and rusty sputum, marked albuminuria and leukocytosis; he became delirious, and just as a distinct drop in temperature and a clearing of the mind made one wonder if recovery after all might be a possibility, he died suddenly. Necropsy disclosed pneumonia of the lower lobe of the right lung and several infarcts in other portions of the same lung.

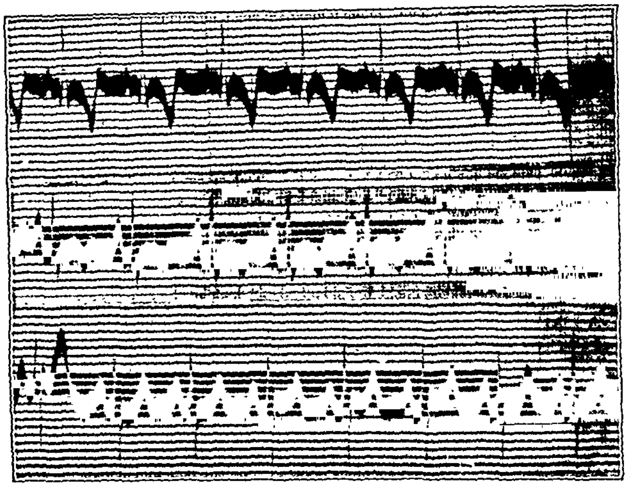

Fig. 3 (Case 3).—Electrocardiogram taken May 3, 1917, forty-one days after the coronary obstructive symptoms. Digitalis not used at this time.

The heart was large—the left ventricle at the apex, the lower interventricular septum and the papillary muscles, especially the anterior one, thinned, scarred and cutting like gristle. The descending branch of the left coronary and the large descending branch of the left circumflex were completely obliterated by old thrombi. The only sclerotic changes in the arteries were a few small patches in the aorta close to the openings of the coronary arteries, and similar patches in the coronaries themselves. It may be added that no history or stigmata of syphilis were noted during life, and that the Wassermann test on the blood had been negative.

According to the necropsy record made by Dr. Thacher of the Presbyterian Hospital, Oct. 8, 1917, the heart weighed 415 gm. The enlargement involved both sides of the heart. The external surface was fairly normal in appearance with the exception of a pale, depressed area 4 cm. in diameter midway between the base and apex of the left ventricle and a smaller similar area on the lateral surface close to the apex. The wall of the left ventricle near the apex and the interventricular septum were thin and of gristly consistency, cutting with marked resistance. The endocardium of the left ventricle had a pale, mottled appearance especially marked over the lower three quarters of the septum and the papillary muscles. The papillary muscles were smooth, contracted and firm, these changes being particularly marked in the anterior muscle. The greater extent of the fibrous changes in the endocardial and subendocardial tissues as compared with those on the external surface of the heart was striking. The left coronary artery contained an organized thrombus in the ramus descendens anterior 3 cm. from its origin. Also the first descending branch of the circumflex was occluded 1.5 cm. from its origin. The coronary arteries showed sclerotic plaques scattered throughout most of their course, these spots varying in size from 0.5 to 2 mm. in diameter. The aortic leaflets were thickened. There were a few sclerotic areas in the suprasigmoid area of the aorta.

EXPERIMENTAL WORK

I wish to call attention briefly to certain experimental work that has a direct bearing on the question of obstruction of the coronary arteries. At my suggestion, Dr. Fred M. Smith[2] in the Presbyterian Hospital and Rush Medical College studied experimentally the coronary arteries in dogs.

Method.—He took an electrocardiogram of each dog when under ether. Then the desired branch of the coronary artery was ligated. Following the operation electrocardiograms were taken at intervals varying from a few minutes to many days or weeks. On all dogs that died or that were killed a postmortem was made, and the gross and microscopic structure of the myocardial lesion was studied. Electrocardiograms were compared to see if there was uniformity in the tracings made after ligation of the same arteries and with the same lesions. Lastly, in human beings with

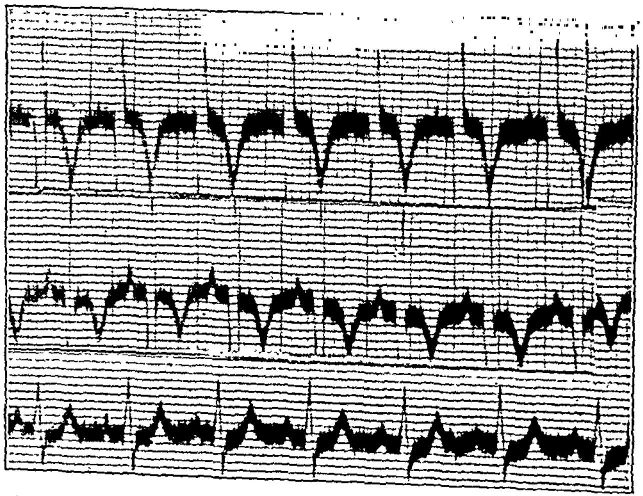

Fig. 4 (dog).—Electrocardiogram taken two days after ligation of anterior and posterior descending branches of the left circumflex artery.

---

[2] Smith, F. M.: The Ligation of Coronary Arteries with Electrocardiographic Study, Arch. Int. Med. 22:8 (June) 1918.

symptoms suggestive of coronary thrombosis, the electrocardiograms were compared with those in dogs.

Results.—The results may be thus summarized:

1. Dogs may live days or months or may recover after ligation of branches of the coronary arteries, even branches of considerable size. This is contrary to the findings of Cohnheim, but is in accord with those of Porter, Miller and others.

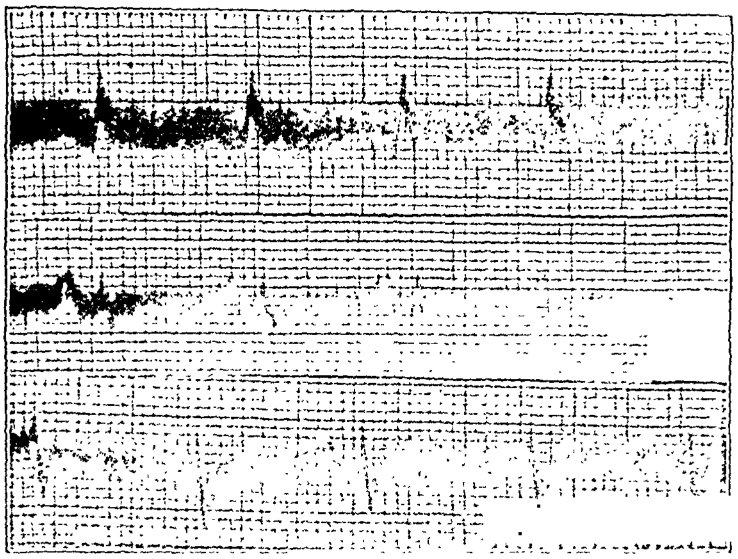

Fig. 5 (Case 3).—Electrocardiogram taken Sept. 27, 1917, 178 days after coronary thrombosis.

2. After the ligation of special branches, the lesions produced in the muscle are fairly constant. These lesions are most marked in the endocardial and subendocardial tissues, that is, in the conducting region. These findings may be compared with those of Oppenheimer and Rothschild.

3. Following the ligation, numerous irregularities, such as extrasystoles, tachycardia, auricular fibrillation, auricular flutter and ventricular fibrillation, may result. Thus far it has been impossible to predict the type of irregularity that will follow a ligation.

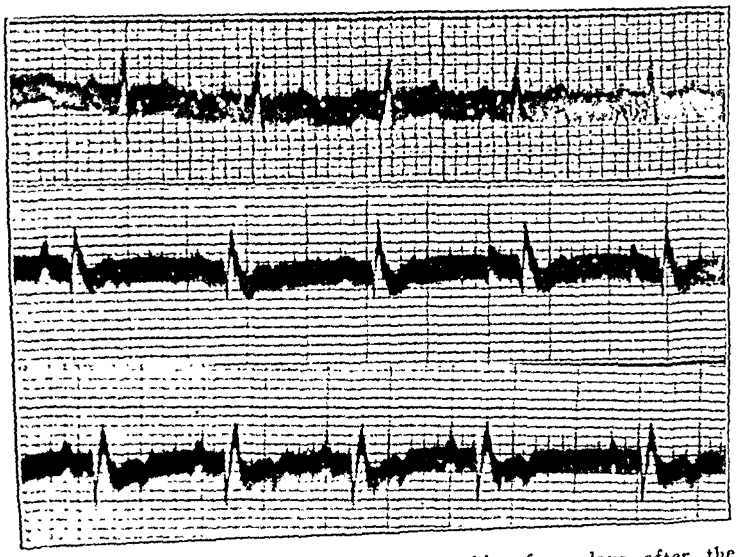

Fig. 6 (dog).—Electrocardiogram taken thirty-four days after the ligation of the ramus circumflexus sinister. Compare this low voltage tracing with Figure 5.

4. There seems to be a fairly constant variation in the electrocardiogram following the ligation of a particular branch of the coronary.

5. There is some hope that the work may assist in interpreting abnormal human electrocardiograms. The thought has been that if it can be proved that with a certain artery obstructed there is a definite lesion in the heart muscle or in the conducting system, and if with that lesion there is a definite electrocardiogram, may we not; when we encounter that abnormal electrocardiogram in the human being, particularly if he has had symptoms suggestive of coronary thrombosis, be able to state with a reasonable degree of certainty that the patient has had obstruction in a particular portion of the coronary system? May it perhaps be possible to localize a lesion in the coronary system with an accuracy comparable to that with which we locate obstructive lesions in the cerebral arteries?

NEED OF CONFIRMATION

This work needs confirmation as to the regularity of the results obtained and especially as to the interpretations and conclusions. Confirmation from necropsies is particularly desired. Patients with this condition do not present themselves very often. A large proportion with coronary obstruction die a sudden death, or are too ill to come to the office or to a hospital where they can have electrocardiographic tracings taken. And yet we have been able to take several suggestive tracings in patients in whom we believed these coronary thromboses to have occurred, and in one of the cases, Case 3, in which the patient lived five months after obstruction, the abnormal electrocardiograms gave helpful confirmatory evidence. Necropsy revealed the lesions anticipated.

TUBERCULOSIS ASSOCIATED WITH MALIGNANT NEOPLASIA

REPORT OF TWENTY CASES *

A. C. BRODERS, M.D.
ROCHESTER, MINN.

To Rokitansky[1] has been given the credit for teaching that tuberculosis and cancer are incompatible diseases; but since McCaskey,[2] in 1902, made the statement that he was strongly inclined to doubt that Rokitansky had ever held to this extreme view, it may be well to quote direct from Rokitansky's article on cyst formation:

> Cyst formation, as a new growth, is rarely found concurrent with tubercle, either in the same organ or in the same organism generally.

With regard to tuberculosis and cancer, he said:

> A similar antagonism, as shown from still more numerous observations, prevails between tubercle and carcinoma. Whenever their general correlation is susceptible of proof, cancer has seemed to succeed to tuberculosis, tubercle rarely to become developed after the extinction of cancer and its crasis.

Also:

> A corresponding result of much interest is afforded by a comparison of the scale of frequency of cancer and tubercle, as well as of several special local relations of both. They are diametrically opposed to one another, as thus:

FREQUENT	RARE
Lung tubercle	Lung cancer
Ovarium cancer	Ovarium tubercle
Salivary gland cancer	Salivary gland tubercle
Stomach cancer	Stomach tubercle
Esophagus cancer	Esophagus tubercle
Rectum cancer	Rectum tubercle
Ileum tubercle, etc.	Ileum cancer, etc.

---

* I [illegible] of Surgical Pathology, Mayo Clinic.

[1] [illegible] Manual of Pathological Anatomy, London, Sydenham 1: 313-314, 1855.

[2] McCaskey, G. W.: The Clinical Association of Cancer and Tuberculosis, with Report of a Case, Am. J. M. Sc. 124: 97-105, 1902.

From the foregoing, it is obvious that Rokitansky did not teach that the two diseases are incompatible but that an antagonism prevails. While a few writers have held to the view that an antagonism exists between active tuberculosis and cancer, by far the greater number are of the opinion that no antagonism exists. McCaskey is apparently inclined to the former view, and he has suggested the systematic local injection of tuberculin in the cancerous tissue in properly selected inoperable cases of cancer. Dabney,[3] writing in 1916, fourteen years later, practically agrees with McCaskey. He has injected the tuberculin in seven cases of cancer, and in one, improvement of the patient's general condition immediately became very marked, and this improvement continued after three months or more of tuberculin therapy. Dabney used, as a basis for his argument in favor of the injection of tuberculin in cancer cases, that it would bring about a lymphocytosis in practically all cases; and as Murphy and Morton, and others have shown that lymphoid activity is an essential factor in the immunity process of artificially engrafted cancer, it would seem that the tuberculosis that brought about a condition of lymphoid activity would exert an inhibitory influence in cancer.

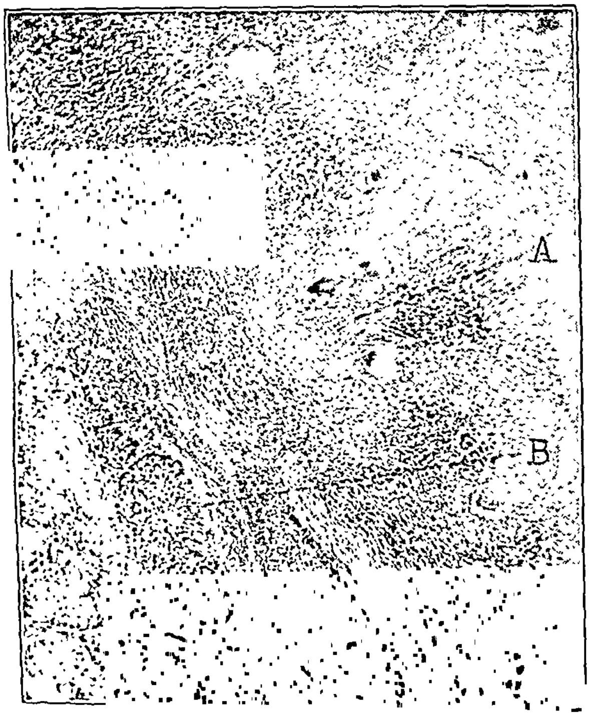

Fig. 1 (A 59139).—Tuberculosis and epithelioma in lymph gland of neck (low power): *A*, tuberculosis showing giant cells; *B*, epithelioma. The patient died.

From time to time the negative side of this question has been most ably defended, not only by observations made at necropsy but also from a surgical pathologic standpoint. The first and one of the most noted defenders of the theory was Lebert.[4] Williams[5] found a history of phthisis in 151 (47.7 per cent.) of 316 cancerous families. Lubarsch,[6] in 1888, found carcinoma in 2,668 tuberculous cadavers in 117 (4.4 per cent.) instances, and in 3,868 nontuberculous cadavers he found the condition in 452 (11.7 per cent.) instances. In 569 carcinomatous cadavers he found tuberculosis in 117 (20.6 per cent.) instances, and in 5,967 noncarcinomatous cadavers he found it in 2,551 (42.7 per cent.). His statistics indicate that carcinoma is found more often in nontuberculous than in tuberculous persons, the proportion being about 3:1 in favor

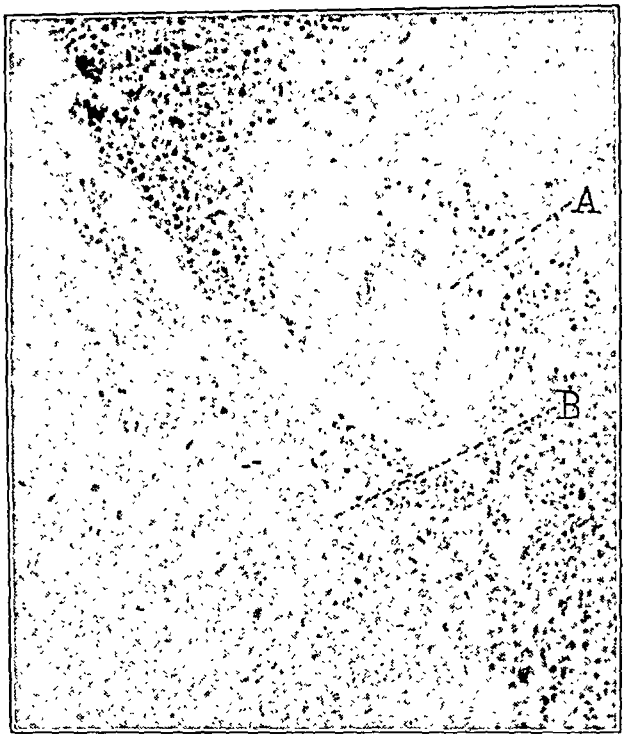

Fig. 2 (A 59139).—Same as Figure 1 (high power): *A*, giant cell of tuberculosis surrounded by epithelioid cells; *B*, epithelioma showing numerous mitotic figures.

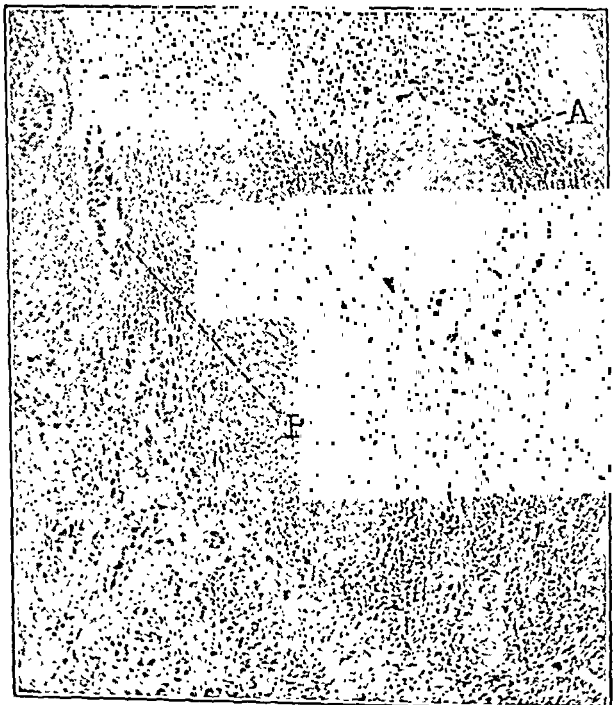

Fig. 3 (A 192320).—Tuberculosis and epithelioma in lymph gland of neck (low power): *A*, tubercle with giant cell; *B*, epithelioma. The patient's condition is unknown.

of the former. He has also shown that tuberculosis is found twice as often in noncarcinomatous as in carcinomatous persons. Moak,[7] quoting Lubarsch, mentions five possible combinations of cancer and tuberculosis:

1. Simple coincidence, the diseases having no apparent action the one on the other.

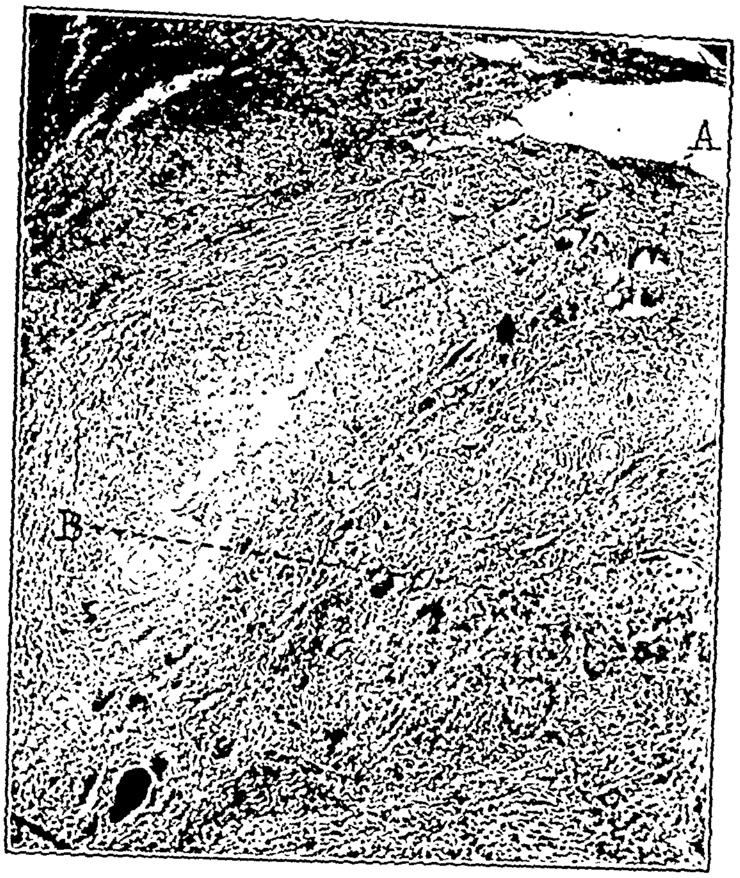

Fig. 4 (A 51290).—Tuberculosis and epithelioma in lymph gland of neck (low power): *A*, tuberculosis, showing necrotic area and giant cells; *B*, epithelioma. The patient is living and well, ninety-one months after operation.

2. Metastatic carcinoma developing secondarily on a recent or old tuberculous focus.
3. A tuberculous infection becoming engrafted on a cancer *in full evolution*.
4. Chronic progressive tuberculosis on which develops a cancer.
5. The simultaneous development of both cancer and tuberculosis.

Naegeli,[8] in 420 necropsies on adults aged more than 18 years, showed that 93 per cent. had either active, latent or healed tuberculosis.

Hoffman's[9] statistics show that in the United States registration area for the year 1913, out of 93,293 deaths from tuberculosis, 73.39 per cent. occurred at ages under 45, and 26.61 per cent. at ages over 45, and that of 49,887 deaths from cancer at all ages, 15.46 per cent. occurred at ages under 45, and 84.54 per cent. at ages over 45.

ANATOMIC LOCATION OF TUBERCULOSIS AND CANCER

Rokitansky and others have pointed out that these conditions are rarely found combined in certain organs, such as the esophagus, stomach, ileum, rectum, salivary glands, lungs, ovary, thyroid and pancreas. I was able to find but five positive and probable cases in which tuberculosis and cancer of the stomach were combined. The two diseases, in most instances, seem to select different anatomic points of origin, and by a metastatic process through the lymph or blood stream they meet at the starting point of one or the other, or at some point remote from their field of origin, such as the lymphatic glands.

Why one tissue or organ should be susceptible to malignant neoplasia or tuberculosis, and another should be, to a great extent, immune, is difficult to explain; nevertheless, such seems to be an established fact.

Tuberculosis associated with sarcoma has been reported by Ricker,[10] Trendweiler[10] and Iscovesco[10] (Moak). Tuberculosis associated with connective tissue malignant neoplasia is rare; the records of the Mayo Clinic show that epithelial tissue malignant neoplasia is about nine times as frequent as connective tissue malignant neoplasia. As an indication of the frequency of the association of tuberculosis with malignant neoplasia, statistics are cited both from necropsy and surgical pathologic standpoints as in Table 1.

CASES FROM THE LITERATURE FOUND BY THE SURGICAL PATHOLOGIST OR AT NECROPSY

Naegeli[11] reported three cases in which tuberculosis and carcinoma were associated. The first patient had carcinoma and tuberculosis of the rectum, the second carcinoma and tuberculosis of the ileum, and the third colloid carcinoma and tuberculosis of the cecum.

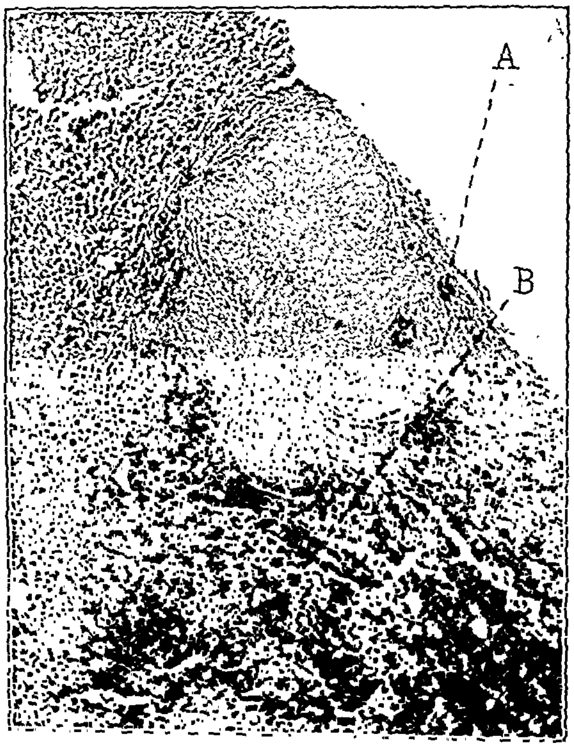

Fig. 6 (A 72500).—Tuberculosis and lymphosarcoma in lymph gland of neck (low power): *A*, tubercle with giant cell; *B*, lymphosarcoma cells. The condition of the patient is unknown.

TABLE 2.—CASES STUDIED IN THE SURGICAL PATHOLOGIC LABORATORY OF THE MAYO CLINIC

Cases		
Males		20
Females		14 (70%)

Rectum—omentum and peritoneum	1 (14.3%)	
PRESENT CONDITION		
Dead		4 (20%)
Living		10 (50%)
Condition unknown		6 (30%)

Three of the four patients who died had malignant metastases in the glands of the neck.

Two of the ten living patients have a recurrence of malignancy, three are in good health, and five have been operated on too recently to be considered. Of the three known to be in good health, 160 months, ninety-one months, and thirty-nine months, respectively, after their last operations, the latter two had epithelioma and tuberculosis in the glands of the neck.

Warthin[12] reported two cases of carcinoma and primary tuberculosis associated in the mammary gland; in the second case both diseases were in the axillary glands also.

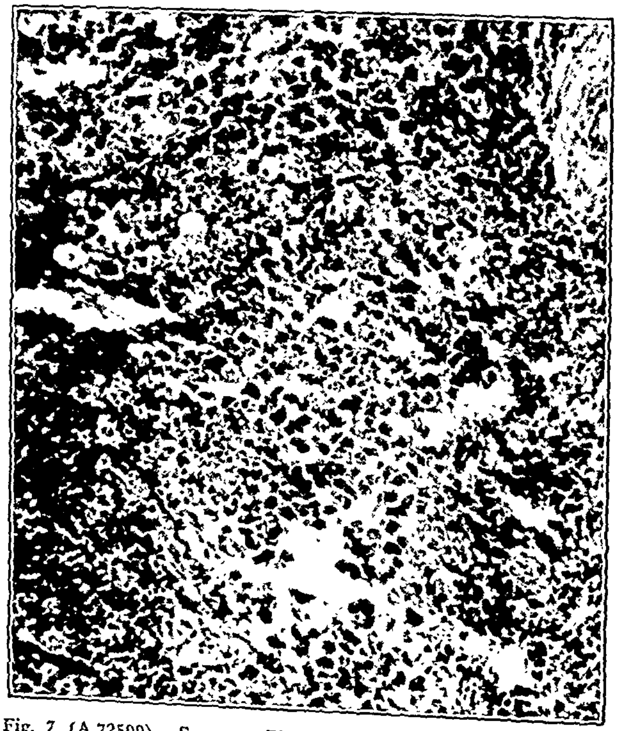

Fig. 7 (A 72500).—Same as Figure 6 (high power): lymphosarcoma cells.

Crowder[13] reported a case of tuberculosis and carcinoma of the cecum with tuberculosis of the lungs, peribronchial and retrocecal lymph glands.

---

[11] Naegeli, O.: Die Combination von Tuberculose und Carcinom, Virchows Arch. f. path. Anat. **148**: 435-448, 1897.

[12] Warthin, A. S.: The Coexistence of Carcinoma and Tuberculosis of the Mammary Gland, Am. J. M. Sc. **118**: 25-35, 1899.

[13] Crowder, T. R.: A Contribution to the Pathology of Chronic Hyperplastic Tuberculosis of the Caecum, Based on the Study of Two Cases, in One of Which Carcinoma of the Caecum Coexisted, Am. J. M. Sc. **111**: 668-693, 1900.

Moak reported five cases of associated tuberculosis and carcinoma. The first case is practically the same as Warthin's second case; the primary tuberculosis and carcinoma in the mammary gland were associated with both diseases in the axillary glands. In the second case, metastatic carcinoma was associated with tuberculosis in an axillary lymph gland. In the third, carcinoma of the mammary gland was associated with carcinoma and tuberculosis in a lymph gland, probably from the axilla. In the fourth, adenocarcinoma was associated with tuberculosis in the sigmoid flexure, and the same combination was in the liver and the left kidney. The fifth case showed an adenocarcinoma and tuberculosis of the lungs, bronchial glands, retroperitoneal hemolymph glands, suprarenal, liver and spleen, secondary to primary carcinoma of the prostate and primary tuberculosis of the lungs. Moak quotes Steinhauser[14] as having collected from the literature eighty-three instances of lupus and carcinoma of the skin, and reported five new cases. Prior to the publication of the articles of Naegeli, Warthin, Crowder and Moak, in 1897, 1899, 1900 and 1902, respectively, a fairly large number of cases showing the association of the two conditions were reported, particularly in Europe, and since that time a fairly small number have appeared both here and abroad.[15]

CONCLUSIONS

1. The theory prevailing among the majority of physicians for a number of years and still prevailing among a few, that tuberculosis and malignant neoplasia are antagonistic, has not been borne out by the facts.

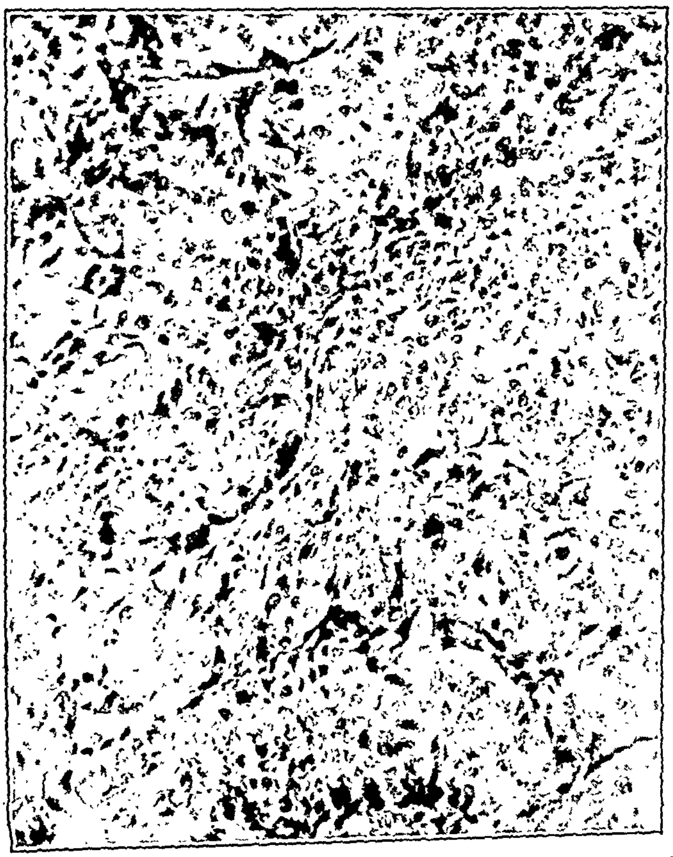

Fig. 8 (A 205751).—Melano-epithelioma of lymph gland of neck (high power).

2. The fact that some tissues or organs are, to a certain degree, *immune* from one or the other or both of these diseases does not prove that the two diseases are antagonistic.

3. If the observations of Naegeli are correct, in which he showed that in 93 per cent. of 420 necropsies on adults more than 18 years of age, either active, latent or healed tuberculosis had been present, then it is reasonable to believe that similar findings should prevail in an equal number of persons who have died with malignant neoplasia.

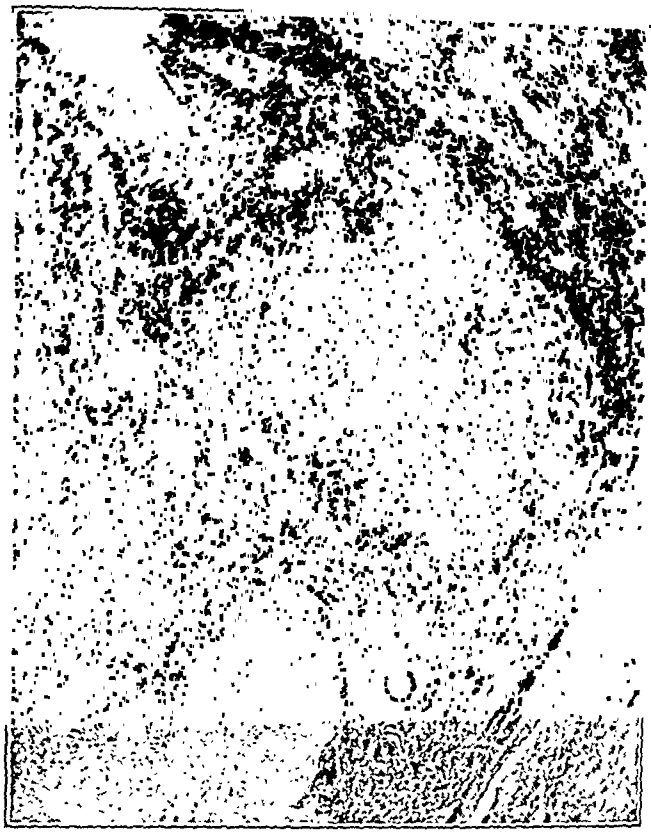

Fig. 9 (A 205751).—Tuberculosis in lymph gland, same as Figure 8, different field (low power). The condition of the patient is unknown.

4. It would seem that the reason pathologists are not finding tuberculosis more frequently at necropsy in persons who have died with malignant neoplasia is that the pathologists are satisfied to find the malignant neoplastic condition, and therefore fail to make a thorough search for tuberculosis.

5. Since the surgical pathologist's examination is limited to the tissue removed by the surgeon, he is greatly handicapped in the search for the two conditions associated, while the pathologist doing a necropsy has access to a large part or the whole of the body.

6. The fact that active tuberculosis occurs most frequently in persons under 45, and malignant neoplasia, especially epithelial tissue malignant neoplasia, most frequently in persons over 45, does not prohibit the association of latent and healed tuberculosis with malignant neoplasia.

7. In our series of twenty cases the two conditions were associated in the same microscopic field seven times (35 per cent.).

Industries Women May Engage In.—Women are capable of doing any and all kinds of work. It is not a question of women and industries, but of the individual woman and the individual job. If the woman is properly selected through physical examination, and is allowed to work under medical supervision, and the occupation is conducted subject to the standards set for hygiene, sanitation and accident prevention, women can do any sort of work which men can do.—*American Journal of Public Health.*

METHEMOGLOBINEMIA DUE TO POISONING BY SHOE DYE

REPORT OF A SERIES OF CASES AT AN ARMY CAMP

RICHARD E. STIFEL, M.D. (CLEVELAND)
Captain, M. C., U. S. Army; Chief of Laboratory, Base Hospital
CAMP JOSEPH E. JOHNSTON, JACKSONVILLE, FLA.

July 18, 1918, a patient was admitted to the base hospital of Camp Johnston in an alarming state of cyanosis. His finger-nails and lips were a deep blue, almost black, yet he complained of no special discomfort. The condition was first noted by friends of the patient, who himself would not have known that he was ill. Examination of the patient was essentially negative, except in the marked cyanosis. The temperature and pulse were normal. Blood taken by puncture of the finger appeared dark. The red and white counts were about normal, but the hemoglobin could not be read on the Tallqvist scale, since it was much above 100. With rest in bed and catharsis, the patient quickly regained his normal color, so that he was well in twenty-four hours.

Following this initial case in July, other cases occurred in August, September and October. By the end of October there had been sixteen cases, in all of which the patients recovered promptly, usually in twelve hours, by rest in bed and catharsis. Many, however, complained of headache, nausea, dizziness and general malaise.

The condition was assumed to be a sulphemoglobinemia, and was so unusual that a special board was appointed by the camp surgeon's office to collect data and investigate these cases. A captain in the Medical Corps was sent from Washington to study the cases, the etiology of which remained in doubt. The general belief was that the condition was due to poisoning or intoxication, or infection by food or water. The possibility of infection by Gaertner's bacillus was kept in mind. The investigator from Washington gathered data, which, though negative, was of value. He found that the cases, while coming mostly from Block A, were not related to any mess, any menu or any particular article of food. Cases occurred on various days of the week. The water supply was ruled out. All the water in this section of Florida was known to contain traces of hydrogen sulphid. While the base hospital laboratory examination of scrapings from one of the tanks during the summer had shown sulphur granules and thiobacteria, the water supply was known to be excellent. Moreover, no cases of cyanosis had occurred in the civil population of Jacksonville, which was furnished water not unlike that of the camp Thus the matter stood, Nov. 1, 1918, when the seventeenth and last case of cyanosis occurred At noon, November 1, a report came to the base hospital laboratory that there was a case of cyanosis in Jacksonville. I accordingly went to the city with the necessary equipment for making a spectroscopic examination and percentage determination of the hemoglobin, a blood count, blood culture and stool culture. I had seen none of the preceding cases. At 2 o'clock, when the patient was examined, he had entirely recovered from the cyanosis

REPORT OF CASE

The patient, Second Lieut. J. M. M., Q. M. C., aged 23, became "blue" at about 6 p. m. the preceding day, and complained of dizziness, headache, and of feeling cold. He went to the home of a friend in Jacksonville, where he was immediately put to bed, because "he looked like the dead body of a drowned man." At 8 p. m., a captain in the Medical Corps was called to see him. Castor oil was prescribed. After thorough catharsis during the night, the patient felt better and his normal color returned. The patient dated his illness to three days before he became blue, at which time he began having slight diarrhea which he thought terminated in the cyanosis. He was the first to notice that he was blue, but it did not alarm him when he saw himself in the mirror, since some of his friends had had the same trouble and had recovered from it promptly. The patient had been eating in Block H, while most cases came from Block A. He had eaten two meals in Jacksonville on the day he became ill and one a week before he took sick. All other meals were taken at his regular mess. He never ate cheese or fish. He did not remember of eating heartily of any dish, except fresh, raw apples, or of partaking of any unusual food or drink, previous to his illness. He believed that the lemonade at his mess might be the cause of the trouble, suspecting that the lemon extract might contain wood alcohol. He stated with certainty that he had eaten no meat for two and one-half weeks before he became sick. Four days before he became blue, and one day before he began to have diarrhea, he began eating meat.

The history thus far suggested the possibility of meat being the etiologic factor. It was only on November 7, when the patient was quite well, that the fact was elicited that he had had his shoes darkened on the day he became ill. He stated that the odor of the dye had seemed pleasant when it was applied, but after the "blue spell" the odor, which adhered to the shoes, was offensive. This was the clue that led to the shoe dye.

THE SHOE DYE

I then interviewed three other men who had been blue, and all of them were positive they had had their shoes dyed the day they became ill, or had worn newly dyed shoes on that day. One man stated voluntarily that his shoes were distasteful to him after he had left the hospital. They all had the work done at "Toney's" boot black stand in Jacksonville. They were all newly commissioned. This fact strengthened the case against the dye, for the necessity of darkened shoes, that is, shoes to match puttees, was felt most by the newly commissioned officers in Block A, who were getting their equipment. The enlisted men in the blocks could ill afford to pay a dollar, which was Toney's price for the dyeing of a pair of shoes. The fifth man interviewed, who had been blue, had also had his shoes dyed at Toney's but he was sure that they had been dyed a week after he was in the hospital. He stated that were this a legal matter involved, he would state the fact under oath. This was disconcerting. However, three additional men who had been cyanotics were found who like the first four, remembered distinctly that their shoes had been dyed the day they went to the hospital. The other nine of the seventeen men had gone overseas and could not be reached.

TEST OF THE DYE

It only remained to get some of Toney's dye and test it in the laboratory. I obtained a few ounces under false pretenses. The name of the manufacturer could not be learned, since Toney had a sort of monopoly of this process of darkening russet shoes, and kept it a secret. The dye was found to be a dark brown, oily liquid with a pleasant almond odor, which soon became suffocating. Some of it was tried on white mice. It was found that 8 drops on cotton, placed in an open half pint Lightning jar containing a white mouse, killed the animal in four or five hours. For a few minutes the animal would not object to the odor of the dye, then it would grow restless and seek to escape, then dyspneic and drowsy and finally unconscious. Before this stage it would recover, if put in the fresh air; after this it would always die. It would become distinctly cyanotic. At necropsy the blood would be almost black and show the presence of methemoglobin by the spectroscope. It now seemed important to try the dye on a human being. This I did on myself, dying my own shoes with some of Toney's preparation. After wearing the shoes four hours, I felt nausea, headache and visual disturbances. Well satisfied with the result of the experiment and enthusiastic for carrying it further on some one else, I removed the shoes. I did not become cyanotic.

November 12, two men in the laboratory, Private Chester Garden and Lieut. E. F. Blair, S. C., having had the matter fully explained to them, volunteered to let me dye their shoes with Toney's dye, by Toney's method. Private Garden was not visibly affected by wearing his shoes six hours, but he complained of headache and nausea, which lasted eighteen hours. Leiutenant Blair, whose shoes were more thoroughly saturated with the dye, after being more thoroughly cleaned with alcohol, became slightly cyanotic in six hours. In seven hours his lips and finger-nails were purple, and he looked ghastly. He had no complaint. His feet "burned" a little, but caused no real discomfort. His blood, obtained by the puncture of the ear lobe, was abnormally dark. The red cells had fallen slightly during the seven hours, from 4,100,000 to 3,900,000. The white cells rose from 9,000 to 12,000, the differential count being unchanged. The hemoglobin by Tallqvist's scale was above 100 and could not be read; it had been 90. By Sahli's it was 95 per cent; it had been 90 per cent. Spectroscopic examination of the blood revealed the normal absorption bands of oxyhemoglobin; sufficient methemoglobin was not present to be detected by a direct vision spectroscope.

NITROBENZENE POISONING

Chemical examination of the dye, later confirmed by the department laboratory, showed the presence of nitrobenzene, also called nitrobenzol, and in trade, oil of mirbane. It is an oily liquid with the odor of bitter almonds, which sometimes produces poisoning in the coal-tar color industries, explosive works, and pharmaceutic laboratories, poisoning whose symptoms are nausea and vomiting, headache, vertigo, tinnitus, visual disturbances, local burning sensation, dyspnea, and marked cyanosis with the formation of methemoglobin. The presence of nitrobenzene in a shoe dye was not surprising to one of the oldest and largest manufacturers of shoe dyes and polishes in this country, since such dyes contain anilin made from nitrobenzene. This firm had never heard of poisoning as a result of wearing dyed shoes.

It is interesting to note that poisoning by nitrobenzene, while unusual, is not unknown. Blyth[1] notes a case in which death of a man resulted in nine hours by the accidental spilling of nitrobenzene on his clothes. It will be surprising if similar cases of cyanosis have not occurred at other camps. I have a record of one case at this camp in which the dye was not bought at Toney's, but at a well known shoe firm in Jacksonville, which has branch stores in all of the large cities.

The poisonous properties of these dyes are soon lost from the shoes. In three or four days after the shoes have been dyed, it is apparently safe to wear them.

FURTHER OBSERVATIONS ON SEX GLAND IMPLANTATION

G. FRANK LYDSTON,[1] M.D.
CHICAGO

I desire first briefly to present observations of several cases hitherto reported, with special reference to the present condition. The first of these cases was exhibited at the Urological Society of Chicago in October, 1917, and the second at the November, 1917, meeting.

CASES ALREADY REPORTED

Case 1.—At the age of 17 an injury to the right testis was sustained. This was followed probably by a hematocele and traumatic orchitis. When the swelling subsided the gland had "entirely disappeared." The left testis atrophied to a moderate degree subsequent to the injury. Virility was unimpaired, but the patient developed distinctly feminine secondary sex characteristics.

At the age of 29 an infection of unknown character attacked the remaining testis, with resultant pain in the left iliolumbar region, left spermatic cord and testis. The clinical history of the case at that time is not available. According to the patient's story, the testicle did not swell, but there was considerable fulness of the spermatic veins. Within three weeks the organ had completely atrophied, and some weeks later the case was referred to me.

At the time of my examination the patient was of healthy appearance, but excessively fat. The beard was almost negligible, the mammae moderately large, and the pelvis distinctly feminine. Sexual power, which had been "satisfactory" until after the loss of the second testicle, had entirely disappeared. During the years subsequent to the original injury the patient had not been physically as fit as before, and for about a year he had been physically and mentally quite inefficient, which inefficiency rapidly increased after the loss of the remaining testicle.

Palpation disclosed scarcely a vestige of tissue at the end of the spermatic cords. Only a small body somewhat larger than a grain of wheat could be felt on each side. The penis was of very moderate development with a long prepuce, but otherwise normal.

Aug. 1, 1915, I implanted on this patient both testes taken from a boy of 14, dead of a crushing injury. The glands were removed six hours after death and placed in sterile salt solution. The operation was performed thirty-nine hours after the death of the donor.

The results of the implantation were extremely satisfactory, the patient regaining his physical, sexual and mental efficiency. There was a marked change in the secondary sex characteristics so far as the excessive fat was concerned.

Nov. 15, 1918, more than three years and three months subsequent to the operation, the patient reported as still in satisfactory condition. He had entirely lost his fat excess and was robust and athletic in appearance. The implanted testes were still in evidence, firm and obviously sclerotic, and about the size of a good sized hazelnut. The remnants of the testes present at the time of operation had increased to the size of a large pea. There apparently had been no decrease in the size of the implanted organs after the first eighteen months.

Case 2.—The patient, aged 19, following vaccination at the age of 13, developed a secondary infection of the testes, resulting in almost complete atrophy of both organs within a few weeks. Coincidentally the penis became distinctly smaller. The case was examined by several surgeons, who diagnosed retained testicle on the left side, and suggested operation. At the age of 17 the patient came under my observation.

The boy was tall and healthy looking, with distinctly feminine secondary sex characteristics. The pelvis, mons veneris, and mammary glands were suggestive of a girl just entering on puberty. No beard was in evidence. There was a bare suggestion of hair on the pubes. The left testicle was a small, soft, barely perceptible nodule about as large as a small pea, just below the external inguinal ring. The right testicle was soft and about the size and shape of a small Lima bean. The penis was no longer than that of a well-developed child of 5 or 6 years of age, slightly "hooded," and suggested an enlarged clitoris. Psychically the boy was normal despite the absence of any signs of virility.

The case passed from under observation and subsequently an ill-advised operation was performed on the left side for "retained testis," with resultant destruction of what little gland tissue remained.

At the age of 19 the boy again reported. Implantation of testes was consented to and the operation performed, Oct. 27, 1916. The material used was taken from a healthy boy, aged 15, dead twenty-four hours of gas poisoning. The glands were refrigerated for thirty-two hours.

The secondary sex characteristics in this case became more masculine, there was a considerable growth of pubic hair, the penis increased greatly in size, and virility was established.

I last examined this patient late in June, 1918, one year and eight months after implantation. The condition of the testes was essentially the same as in Case 1, and apparently they had not grown smaller since the patient was exhibited at the Urological Society in November, 1917. It is interesting to note that this boy passed the Army examination and is now a Second Lieutenant in the U. S. Army in one of our American camps. In a recent letter he reported a considerable increase in the growth of his beard.

ADDITIONAL CASES

CASE 3.—A paretic dement, aged 46, in whom the syphilitic condition had been very insidious, and some six years had elapsed since the symptoms were noticed, had been unable to attend to any business affairs of any consequence for several years and, for obvious reasons, was not permitted to go about the city streets unattended. He complained rather strenuously of loss of sexual power.

In the hope of retarding the progress of the paresis, a successful double implantation was performed in August, 1917. The glands used were taken from a boy, aged 16, dead of accident twenty-four hours. They were refrigerated for thirty hours. The effect of the implantation was in a general way quite remarkable. The patient became brighter and his physicial condition greatly improved. Sexual activity was so increased that he was rather inclined to complain of it. His mental condition was so far improved that he was permitted to go about alone, and was able to attend to a little business. It is proper to state that he had antisyphilitic treatment more or less continuously. The fact remains, however, that the case was at a standstill and there was no marked improvement until the implantation was done.

About fourteen months after implantation, the improvement apparently having continued, the patient suddenly developed violent one-sided convulsions, lapsed into coma, and died. There was no necropsy. A diagnosis of probable cerebral thrombosis was made.

CASE 4.—A man, aged 21, whose sexual organs were congenitally undeveloped, had moderately marked feminine secondary sex characteristics, and his beard was very slightly in evidence. His general physical development was imperfect, the patient being 6 feet 3 inches in height and weighing 130 pounds. There was very moderate sexual activity. Unsatisfactory and unpleasurable experimental coitus had been performed on three or four occasions. The patient complained of general weakness and stated that he had very little physical endurance. There was no sexual psychopathy. There was a fair amount of pubic hair and very moderate penile development. Only on painstaking examination could any suggestion of testes be felt. Several surgeons who previously had examined the patient had diagnosed "retained testes." The glands were about the size of a navy bean, and so soft as to be barely perceptible.

A successful double implantation was performed, June 15, 1918, the material being procured from a boy of 16, dead eighteen hours of a crushing injury of the skull. The material was kept on ice for thirty-six hours.

The patient was examined, Oct. 1, 1918. There had been a marked increase in size and improvement in consistency of the patient's own testes. The physical condition was vastly improved. His color was excellent and he had gained 20 pounds in flesh. As he expressed it, he never felt so well in his life. He said, however, that while erections were more vigorous, he experienced no sexual desire. The penis appeared to be of firmer consistency and slightly better developed than at the time of operation. He had been overindulging in physical exercise, which possibly might explain the lack of desire. Nov. 12, 1918, improvement in the general condition was sustained, but there was still a lack of sexual desire.

The patient again reported for examination Jan. 6, 1918. There had been still further development of his own testes. The implanted glands were in excellent condition and had not appreciably shrunken since the last examination. Sexual power and desire apparently were normal.

CASE 5.—A professional writer, aged 29, suffered from profound sexual neurasthenia, and complained of the entire gamut of symptoms characteristic of such cases. A careful examination that I made and previous examinations by numerous competent neurologists had elicited no organic nervous lesion. (Since the implantation I have discovered floating right kidney.) The pivotal point of his symptoms was simply pain with extreme hyperesthesia of the skin and pain referred to the bladder. As everything else had been tried in this case, I suggested an implantation, chiefly for the psychic effect.

A successful implantation of a single testis, taken from the body of a boy of 17, dead of accident, and preserved on ice in saline solution for thirty-eight hours, was performed, Sept. 7, 1918.

There was marked improvement in the patient's general condition, but no change in the nervous symptoms of which he complained at the time of the last examination, about six weeks after implantation. The implanted gland was slowly atrophying. Nephropexy was suggested as a "possible" source of improvement. How frequently this operation is disappointing in neuropathies the surgeon is well aware.

CASE 6.—A physician, aged 40, complained of neurasthenic symptoms from overwork, associated with an annoying tachycardia.

Implantation was performed at the patient's request, the companion testicle to the one used in Case 5 being employed. Local results were satisfactory.

The patient has not reported recently, but a month after operation he wrote that he was in much better general condition, and that the tachycardia had subsided.

CASE 7.—A man, past 50 years of age, complained of failure of sexual power. He said that sexual intercourse was possible only when he was under the influence of alcohol. The subject is distinctly melancholiac. An implantation was suggested in the hope that the combined psychic effect and the stimulating action of the sex hormone would remedy the obviously psychopathic condition.

Testes taken from a boy of 18, dead of accident, were used, the implantation being done forty-eight hours after the death of the donor. The material was refrigerated for more than thirty hours.

When this case was last heard from, about six weeks after operation, the implanted glands were in excellent condition. The patient stated, however, that he still was unable to perform the act of intercourse except when under the influence of liquor. On one occasion, however, subsequent to the operation, while under the influence of alcohol he indulged, according to his own account, four times in succession, an extent that should be considered excessive for a normal man of his age.

As this patient drifted away from observation, I do not know the present condition of the implanted glands. The patient recently wrote that his sexual status was not improved.

Case 8.—A man, aged 27, had marked feminine secondary sex characteristics and congenitally undeveloped sexual organs. Not only were the testes almost imperceptible, the case having been pronounced one of retained testes, but there was no scrotal development. In order to prepare a field for implantation, it was necessary to "cup" the scrotal region with a vacuum pump for some weeks prior to the implantation. The pubic hair was exceedingly sparse. There was practically no hair in the normal location of the scrotum. The patient was exceedingly spare, being 5 feet 8¾ inches in height, and weighing 120 pounds. The development of the mons veneris and pelvis was especially feminine in character.

Oct. 8, 1918, a double implantation was performed. The material was taken from a boy of 17, dead of accident. The testes were refrigerated in boric solution on ice for forty-eight hours. The implanted glands in this case were quite large, and the pseudoscrotum which I had succeeded in "pocketing" was so thin that I was very apprehensive of sloughing.

There was sloughing of a circular area of the skin about one-fourth inch in diameter over the most prominent portion of the gland implanted on the right side. There was a slight necrosis of the fascia at this point, and there is still a small sinus giving exit to a small quantity of serous fluid. Five weeks after operation the implanted glands were still in good condition and obviously "alive." There has been an increase in the quantity and an increased coarseness of fiber of the returning pubic hair. Quite a quantity of hair is appearing on the lower part of the scrotum. The patient states that he now has vigorous and prolonged erections and that at the time of erection the penis is distinctly larger than before operation. The organ is slightly firmer when flaccid. The patient's color and general condition is much better, his nutrition having greatly improved.

As to the ultimate results in this case, it is to be remarked that at the age of 27 the outcome is much less promising than in cases in which operation was performed at an earlier period. It is my belief that when implantation is done in cases of like character at an age not too far from puberty, results as good as those obtained in Case 2 reasonably may be expected. In such cases as Case 2 reimplantation should be followed by even more satisfactory results.

Dec. 15, 1918, the sinus had closed and the implanted testes were in good condition.

The next case is especially gratifying to me because the operation was performed by another surgeon. Dr. L. L. Stanley, of the California State Prison at San Quentin, was so courteous as to describe the case to me with permission to publish a report of it in connection with this series.

Case 9.—A man, aged 25, evidently a moron, committed for attempt at burglary, had been kicked in the testicle, five years previously, with following inflammation, swelling, and subsequent atrophy. At the time of operation the testes were the size of "olive pits." The patient was tall, thin, anemic, and very dull and apathetic. He originally had been a teamster.

The donor was a negro who was hanged for murder. The glands were refrigerated for some hours. The glands were removed from the donor fifteen minutes after death. An anastomosis of the vas deferens was done on the right side. The left "implant" was inserted partially within the tunica vaginalis and held in place by several sutures, without anastomosis. The testes were not decorticated.

Seven weeks after operation the doctor reported that the testes were firm and were not atrophied and were "resting nicely in the scrotal sac." The patient had gained 15 pounds and had become active and alert—in fact, he was improved in every way—and sexually had become very active.

Three months after operation, the right testicle had atrophied slightly, but was still firm and well shaped. The left testicle was in excellent condition. The doctor said: "He now has erections nightly and frequently in the daytime, something he has never had before. He is much stronger and livelier and gets about much more actively. It is reported that whereas before he was slow and inactive and seemed about 'half dead,' he now speaks out quickly, has improved mentally, and has livened up to a marked degree. He now will 'square away' if anybody 'quips' him, and he can make a quick retort, whereas before he would pay little attention to any offense offered him."

COMMENT

The course of all these cases was practically afebrile and attended by no pain during the postoperative treatment. In Cases 4 and 5 the patients complained of some reflex pains in the spermatic cords for a few weeks subsequent to implantation.

I wish to note especially the result obtained by Dr. Stanley, particularly in the matter of "cross-racial" implantation. Should the testes in this case permanently endure or atrophy no more slowly than when the donor is of the same race as the recipient, it biologically would be a most interesting and a practically valuable observation.

That there is any advantage in the anastomosis of the vas is open to question, first, as to the betterment of nutrition, and secondly, as to the preservation of spermatogenic function. I myself believe that we run more risk of failure of the implant from the greater traumatization of the tissues necessary for anastomosis. Then, too, it is my belief that the spermatogenic epithelium of the tubules degenerates in all cases rather promptly. This, however, is a point that can be determined only by examination of the semen, as to which Dr. Stanley has not yet reported. As bearing on this point, I wish to recall a case of my own in which a fistula formed and persisted for five or six weeks after the implantation of a decorticated gland. The secretion from this fistula contained immature spermatozoa. In dissections that I have made of implanted testes at various times after operation there apparently has been an extensive proliferation of the cells of Leydig and a coincidental encroachment on and destruction of the spermatogenic tissue proper.

An observation which seemingly is worthy of note is the fact that the implanted glands atrophy and disappear more rapidly when the recipient has well-developed testes of his own. The apparently permanent local results thus far obtained were in cases in which the patient had very little gland tissue, as in Cases 1 and 2. A sort of "parasitic" action of the patient's own glands on the implanted organs suggests itself. Possibly the patient's testes appropriate nutritive pabulum which otherwise might be available for the implanted organs. In any event, therapeutic results are obtained and sustained even when the implanted glands eventually disappear. When, as in Cases 1 and 2, the patient's own remnants of testis tissue develop after the implantation, it is reasonable to expect permanence of any improvement that occurs in the patient's condition.

Since this paper was written, I have examined a patient whose case was previously reported, on whom an implantation was done at the age of 69 for possible improvement of senility and failing sexual power. The results in this case were eminently satisfactory, and nearly two years later still endure, although the implanted glands practically have disappeared.

25 East Washington Street.

TRENCH FEVER

A CRITICAL REVIEW [*]

WILDER TILESTON, M.D.
NEW HAVEN, CONN.

In the spring of 1915 there began to appear in the British army in France a large number of cases of an acute infection resembling influenza. More careful investigation, however, soon showed that the disease was not influenza, but a new clinical entity. Since the early cases arose chiefly among the soldiers at the front line, the name "trench fever" soon came to be used.

The disease was described first by Graham[1] in September, 1915, while the designation "trench fever" was used first by Hunt and Rankin,[2] who gave an excellent clinical description of the disease.

Briefly, trench fever is characterized by the sudden onset of fever, with dizziness, headache, backache, and pains in the legs, which later become localized in the shins. The temperature curve is often characteristic, showing an intermission on the third or fourth day, followed after an interval of a day or two by a second rise. The final defervescence takes place at about the eighth day, and is followed by one or several relapses at fairly regular intervals. There is no mortality.

The disease has been and is very prevalent in the British army in France, though apparently it is much less common in the French, German and Italian armies. It has been reported only in isolated instances in the British armies operating elsewhere. A few cases have been reported in England among those brought in contact with soldiers invalided home from France with the disease.

As first encountered, the disease occurred only in two groups of men: (*a*) those who had been recently in the front line trenches, and (*b*) the personnel of hospitals in which trench fever patients were being cared for. Later it became more widely disseminated.

SYMPTOMS

The onset of the disease is usually sudden; those affected may fall while on duty. The first symptoms are dizziness, headache and pains in the lumbar region and legs, associated with fever. Chilliness is common, but true chills are unusual. There may be vomiting. Headache is not very severe, is most often frontal, and frequently is referred to as behind the eyes, which may be painful on motion. Exceptionally the headache may be occipital and associated with stiffness of the neck, so that the suspicion of meningitis arises.

The lumbar pain may be so severe at the onset that smallpox is suggested. In the legs it appears at first to be muscular in its seat, later becoming localized to the tibiae; it is rarely in the joints. There is often pain in the splenic region. Abdominal pain is common, and is either generalized, or confined to the right lower quadrant or the left hypochondrium. Appendicitis may be simulated. The pain is usually accompanied by well-marked hyperesthesia of the skin, most often on the outer aspect of the legs, but also on the thighs and in the precordial and left axillary regions. This hyperesthesia constitutes a sign of considerable diagnostic importance, as it is rarely seen in the diseases likely to be mistaken for trench fever.

Prostration is often very marked, or it may be almost lacking. Constipation may be present, but it is not the rule, and diarrhea is absent.

On physical examination, the eyes are bright; the conjunctivae, as in so many acute infectious diseases, are almost invariably injected, but there is no exudate. Nystagmus on lateral motion of the eyes occurs in about 85 per cent. of the cases; it is an early sign and persists throughout the disease; and since it is seldom seen in other acute infections, it constitutes a valuable diagnostic sign. Herpes is rare. The tongue is clean or slightly coated. The respiratory tract, in contrast with influenza, shows no signs of inflammation. The pulse rate is usually low in proportion to the fever during the original attack, but with relapses there is a tendency toward tachycardia.

Many writers have stated that the spleen is not enlarged, but this is an error. In the experimentally produced disease, the American Red Cross Commission[3] found palpable enlargement at some period of the disease in 85 per cent. of the cases, and within a few hours of the onset in 25 per cent. The enlargement may be first encountered at almost any stage of the disease, and persists for a variable period, sometimes only for a day or two. These facts probably account for the failure of many observers to detect the enlargement, which is usually quite moderate in degree. In the disease as it occurs in nature, the frequency of splenic enlargement is probably about the same as in the infection when produced experimentally.

A characteristic rash appears in about 50 per cent. of the cases, but it is so evanescent that it has been overlooked by most observers. It is well described by Drummond,[4] and by the American Red Cross Commission.[3] It consists of scattered red macules, about the size of rose-spots, disappearing with pressure and rarely elevated. It occurs chiefly on the trunk, in successive crops, during the original attack, and in relapses.

Examination of the blood reveals in most cases a leukocytosis during the primary attack and in relapses.[5] In some cases, however, leukopenia occurs. At the time of a relapse the picture is more or less characteristic, in that neutrophils, lymphocytes and large mononuclears are all simultaneously increased. The red cells show nothing of importance. The urine rarely shows albumin and casts.

TEMPERATURE

According to McNee, Renshaw and Brunt,[6] two types may be distinguished, the short and the long. In the former there is usually an intermission of the fever about the third day, followed by a rise after a day or two of normal temperature; the patient becomes afebrile at the end of seven or eight days and either recovers promptly or suffers a single relapse.

The long type shows a very characteristic temperature curve, owing to the presence of relapses. These are usually three or four in number, and are often spaced at regular intervals, resembling in their periodicity the febrile attacks of rat-bite fever. The interval between relapses ranges from four to thirteen days, but is usually fairly constant for the individual case. The temperature during the relapse is often as high as in the original attack, but rarely remains up for more than thirty-six hours, so that the chart has a "spiky" appearance. There is a tendency for the fever to be lower with each succeeding relapse. Between the attacks the patient feels fairly well, though slight pains in the shins, aggravated at night, serve to remind him that he is not through with his disease. During the relapse the symptoms of the original attack recur with more or less violence.

During the summer of 1915, according to these authors, the short type was much the more common, but in the following winter the long type[7] was encountered more frequently. Since this form incapacitates the soldier for from four to six weeks, and occasionally for months, trench fever causes a very considerable wastage of men.

In addition to these two types, there should be added a more chronic one, which has received little attention from writers at the front because such cases are invalided back to England. Here, following a typical history of acute trench fever, there is a chronic state of ill health. The patient suffers from pains in the shins, aggravated at night and on exertion. The temperature is not quite normal, but shows a slight rise to 99.5 or 100 in the evening. From time to time there is a slight further rise in the temperature with increase of the pain. Such a condition may last for many months.

Complications are conspicuous by their absence. A fairly common sequel is the condition variously labeled "soldier's heart," disordered action of the heart (D. A. H.) and effort syndrome (Lewis). Among the numerous cases of this condition seen by the reviewer at the Military Heart Hospital at Hampstead, the onset could often be traced to an attack of trench fever.

ETIOLOGY

That trench fever is caused by an infectious organism was proved by the work of McNee, Renshaw and Brunt.[6] These investigators were able to transmit the disease to healthy soldiers by the intravenous or intramuscular injection of whole blood obtained from cases of trench fever, and the blood of such experimental cases was found capable of causing the disease in other soldiers. Experiments with washed red corpuscles were also successful, while those with plasma and serum were inconclusive. Filtered plasma and serum, and filtered extracts of the red corpuscles were found incapable of producing the disease. They concluded that the organism was probably contained in the red blood corpuscles or in the leukocytes, and that it was not filtrable.

These experiments have been recently confirmed by the Trench Fever Commission of the Medical Research Committee, American Red Cross, headed by Major R. P. Strong.[8] Very carefully controlled experiments were made on healthy volunteers from the American army in France. Fifteen out of sixteen soldiers inoculated with whole blood, and three out of four inoculated with washed red corpuscles, developed the disease. In contrast to their predecessors, however, they obtained positive results in all five cases inoculated with plasma. Plasma, serum, and extracts of red corpuscles, after filtration through a Berkefeld filter, were found incapable of reproducing the disease. The blood was proved to be most infectious during the first two days of fever, and more so in the original attack than during a relapse. The authors concluded that the organisms were contained in the blood, particularly in the plasma, and that some were thrown down with the red cells in the process of centrifugation.

The search for the organism thus far has led to conflicting results. The marked tendency to relapses at rather regular intervals is very suggestive of a spirochetal origin of the disease. There is close resemblance of the temperature charts to those of rat-bite fever and relapsing fever, two diseases known to be caused by spirochetes. Thus far spirochetes have been found in the urine in trench fever by Nankivell and Sundell,[9] by Patterson,[10] and by Reimer.[11] The first named found them in twelve out of fifteen cases. They were present in small numbers and not on all occasions, being most often found from the fourteenth to the sixteenth day. The work of Stoddard,[12] however, has shown that great care must be used in interpreting the presence of spirochetes in the urine. He found spirochetes of various shapes in the urine, and in urethral smears in 33 per cent. of 100 healthy men. He noted no difference in the spirochetes in smears in trench fever patients from those in healthy controls.

Dimond[13] reported the finding of hemogregarines in the peripheral, splenic and hepatic blood in twelve cases of trench fever. This organism is a protozoon hitherto found in lizards, rats and dogs, but not in man. His findings have not been confirmed as yet, and his published work is far from convincing.

Blood cultures have always yielded negative results, except in the hands of Houston and McCloy,[14] who reported the presence of the enterococcus, a variety of streptococcus found in the normal intestinal tract. Animal inoculations with the blood of trench fever patients have remained negative.

METHOD OF TRANSMISSION

That trench fever is contagious there can be no doubt. In many instances soldiers have been infected by sleeping with sufferers from the disease, and hospital orderlies often have taken it from patients in the wards. The circumstances under which it arises suggest strongly that it is in some way connected with the living conditions in the trenches. Hunt and McNee[7] state that a history of lousiness was obtained in most of their patients.

That the usual method of transmission is through the body louse is rendered certain by recent experimental work. Davies and Weldon[15] were the first to convey the disease in this way, obtaining a positive result in one out of two experiments in which lice were put to feed on trench fever patients and then on the authors. To prove the point, much more extended experiments were necessary, and these have been recently forthcoming at the hands of the American

Red Cross Commission,[3] already referred to. Twenty-two men were exposed to infected lice, and four to noninfected lice, while eight were kept as controls under similar conditions, but free from lice. From twenty-five to 100 lice were placed on each volunteer, after feeding on patients with trench fever, and were allowed to remain for thirty days, or until trench fever developed. In certain cases one half of the lice were removed from the first volunteer from forty-eight to sixty hours after the time of feeding on the trench fever patient, and transferred to a second volunteer. Twelve of the twenty-two men exposed contracted the disease, after an interval of from sixteen to thirty-five days. In four cases the second volunteer developed trench fever, the first volunteers having been previously exposed to the lice for about two days. This renders it probable that the infection was not directly mechanical, but that the lice really harbored the organisms. The controls remained healthy.

The method of transmission was still further elucidated by the work of Byam and his associates.[16] They found that biting by infected lice was not of itself sufficient to transmit the disease, but that the excreta of such lice, rubbed into the scarified skin, would do so with great regularity. The excreta were found to be infective only after an interval of seven days or more after feeding on the trench fever patient; this fact suggests the possibility that the organism undergoes a developmental cycle within the louse. Lice were found to remain infective for a period of at least twenty-three days after feeding on the patient. These experiments indicate that infection in nature probably occurs by rubbing in the louse excreta in the process of scratching.

NATURE OF THE VIRUS

The experiments with filtered blood, already described, all proved negative. A filtrable organism, however, is often held back by the filter when contained in a colloidal solution, such as blood. The Red Cross Commission was able, however, to infect with filtered urinary sediment, and with filtered louse excrement extract, so that the organism may be regarded, for the present at least, as a filtrable one. The virus resists drying and moist heat at 60 C. for thirty minutes, a temperature that kills lice and their ova. They are killed, however, by a temperature of 70 C. for thirty minutes.

The question of immunity after an attack of trench fever is difficult to answer, on account of the long interval of good health that may obtain between relapses. Byam, however, was able to infect a patient who had completely recovered from the disease, while four other patients with chronic trench fever proved refractory.

The incubation period of the disease when produced by the inoculation of blood varies from five to twenty-four days, and in the experiments with lice from sixteen to thirty-five days. In the disease as it arises under natural conditions, it appears to be from fourteen to twenty-four days.[7]

In the absence of fatal cases, the pathology remains unknown.

DIFFERENTIAL DIAGNOSIS

The disease most likely to be mistaken for trench fever is influenza, using the term in its wide sense to include all griplike attacks, whether due to the influenza bacillus or to the streptococcus, *Micrococcus catarrhalis*, etc. The two diseases have in common the sudden onset with fever and generalized pains. The prostration, however, is usually less in trench fever than in influenza, and there are no signs of inflammation of the respiratory tract, while in influenza the shin pains and relapsing type of fever are absent.

From dengue it is distinguished by the character of the eruption, the presence of leukocytosis, and by the fact that dengue has never been reported north of the forty-first degree of latitude.[17]

Relapsing fever is easily excluded by the examination of the blood for spirochetes, and rat-bite fever by the history, the absence of enlargement of the regional lymph nodes, and the different type of eruption.

From typhoid fever and Malta fever it is readily differentiated by the clinical course and by cultural and serologic methods.

PROPHYLAXIS AND TREATMENT

The prevention of trench fever, like that of typhus, rests principally on efficient methods of destruction of lice. If the patients are kept free from lice, isolation is not necessary. Since the blood has been shown to be infectious during a relapse, patients should not be returned to duty until it is unlikely that more relapses will occur.

Up to the present, no effective method of treatment has been devised. The early employment of rest in bed probably shortens the course of the disease. For the pain the salicylates or coal-tar products may be sufficient, but morphin is necessary in the severer cases. Dimond[13] reports relief to the pain in chronic cases from the use of lumbar puncture. The injection of the serum of convalescents has been tried, but without success. Arsphenamin is ineffective. For the symptoms of irritable heart in chronic cases, Byam recommends thyroid extract.

Those especially interested in the subject should study the report of the Trench Fever Commission of the American Red Cross,[3] which contains detailed reports of its experimental work, and of the clinical aspects of the disease as experimentally produced, together with a complete summary of the literature.

Milk.—The National Commission on Milk Standards, after receiving reports on prices paid for milk to the producer and prices at which milk is sold to the consumer, and the mortality statistics from a number of the large cities of the country, has made the following statements regarding milk: The price of milk to the consumer from 1914 to 1918 has in general increased from 50 to 100 per cent.; the quantity consumed has fluctuated, but at the time of the report was not less than the normal of usual supply; there has been an improvement in infant mortality and a lessening of diarrheal diseases among children under 2 years of age, and this improvement has not been checked by the advance in the price of milk between 1914 and 1918; there is evidence of serious condition of undernourishment among children of school age, due, as the commission believes, to improperly regulated diet, and to poverty, but to a larger extent to lack of appreciation of the value of milk as compared with other foods; other foods have increased in price in greater proportion than milk; even at present retail prices milk is the most economical animal food that can be purchased; good nutrition cannot be secured on diets from which milk, eggs and leafy vegetables are absent, and the use of these classes of food should be extended.

OUTBREAK OF TYPHOID FEVER AMONG AMERICAN TROOPS IN ENGLAND *

C. B. HAWN, M.D. (Albany, N. Y.)
Captain, M. C., U. S. Army

J. D. HOPKINS, M.D.
Captain, M. C., U. S. Army

AND

F. M. MEADER, M.D. (Albany, N. Y.)
Major, M. C., U. S. Army

LONDON, ENGLAND

July 11, 1918, there appeared at an American rest camp in England the Fourth Casual Company, J. A. R. D., Camp Cody. Soon after its entrance to the camp several soldiers with fever were brought to Camp Hospital No. 34. At the time many cases of influenza were present among the soldiers who were passing through this camp, so that no special significance was attributed to the symptoms they presented. After a few days' observation the commanding officer of Camp Hospital No. 34 suspected that the cases might be typhoid fever. At about the same time the commanding officer of Camp Hospital No. 36 transferred a few patients to U. S. Base Hospital No. 204. Suspicion of typhoid fever was soon aroused, and blood cultures were ordered by the attending medical officer. The district sanitary officer of United States troops inspected the patients and took specimens of blood in all of the cases. *Bacillus typhosus* was isolated in eight out of ten cases two days later. During the next month *Bacillus typhosus* was isolated from the blood or feces in ten more cases. Altogether, thirty-eight soldiers developed typhoid fever. *Bacillus typhosus* was isolated in eighteen of these cases.

EPIDEMIOLOGY

The organization left Camp Cody, Deming, N. M. June 15, 1918, for Camp Merritt, N. J. While en route, June 18, the organization stopped at Meridian, Miss., and was taken for a swim in a lake. The organization arrived at Camp Merritt, June 21, embarked, June 28, and arrived at Liverpool, July 10. After disembarkation the organization proceeded to the rest camp at Romsey, England. At the British port of debarkation, three cases were left at Red Cross Hospital No. 4, and it is reported that two other cases were left at some station en route to the camp. At the American Rest Camp forty soldiers were found ill and transferred to United States Base Hospital No. 204, where a diagnosis of typhoid fever was made on thirty-eight of them.

From a study of the history of each case it was noted that the date of onset varied over a period of about a month. The first patient was ill on leaving Camp Cody. The second case developed, June 19; the third, June 21; the fourth, June 24; three developed on the 26th, four on the 29th, and five, July 6, after which a case developed every day up to the time the organization arrived at the American rest camp at Romsey.

The organization left the American rest camp before the diagnosis of typhoid fever had been established, and it has since been learned that fifty-seven other cases developed. This makes ninety-eight cases from a total of 248 men.[1]

In seeking the sources of the infection of this outbreak, we naturally turn to the patient who was first ill:

F., 1416995, W., private, Fourth Casual Company, J. A. R. D., *Camp Cody*, the onset of whose illness seems very obscure, stated that he had rheumatism at Camp Cody all the time he was there. He said that he was at the base hospital for two months. He stated that he did not feel well when he left Camp Cody and did not feel any different en route. He proceeded with his company to the American rest camp at Romsey, England, and was admitted to the hospital, July 11, with a doubtful diagnosis. He was transferred to U. S. Base Hospital No. 204, July 16. The patient's temperature and pulse curves would indicate that his illness had continued for a considerable period. It was quite typical of a convalescent period of typhoid fever. This patient went with the company to bathe in the lake at Meridian, Miss.

The service record shows that inoculation with triple typhoid vaccine was completed, Oct. 23, 1917, and paratyphoid vaccine, Oct. 28, 1917. The patient stated that he received at Columbus, Neb., five doses and at Camp Cody two doses of typhoid vaccine.

Another history also is of interest in connection with the source of this outbreak:

B., 1415881, W., private, Fourth Casual Company, J. A. R. D., Camp Cody, stated that he did not feel well when he left Camp Cody, June 15, and that he had stomach trouble and severe diarrhea en route to Camp Merritt. He said that at Camp Merritt the doctor gave him some pills to relieve his trouble. The illness continued during his voyage across the ocean. He continued with his company to the American rest camp and was admitted to Camp Hospital No. 34, July 11, with no diagnosis and was transferred to U. S. Base Hospital No. 204, July 14, as a suspected case of typhoid fever. The clinical record of this case shows that when the patient first entered the hospital his fever and pulse rate was lower than it was three or four days later, so that probably the real date of the onset of his typhoid fever was about July 10. One should, however, note that this increase in fever beginning about July 10 may have been a recrudescence of typhoid fever which began at the time he left Camp Cody.

The patient's service record states that inoculation with triple typhoid vaccine was completed, Oct. 30, 1917. The patient stated that he received three doses of typhoid vaccine at Camp Dodge.

From Table 1 it will be noted that a considerable group of cases developed during the latter part of June and early part of July. This suggests a common source of infection. There are two possibilities:

These patients became infected either in the train early in the journey or by bathing in the water at Meridian, Miss., June 18. The water may easily have been infected by one or two typhoid patients that were present in the organization at the time. In the remaining cases of typhoid the men undoubtedly received their infection by contact with the patients who were ill in the organization. This could easily be done since the men were crowded together on the train or on shipboard.

There were about 1,800 men on board the steamer, which number was composed of Casual Companies 4, 10, 11 and 15, and Supply Company 112. Most of these organizations went on to France, and among the members of Casual Company 4, fifty-seven other cases developed, as is mentioned above.

All of these patients had been inoculated with either typhoid vaccine and paratyphoid vaccine or triple typhoid vaccine or both. Many of them had received several doses in excess of the required number, and the men were inoculated at widely different posts and at different times. One patient says that he received but one dose; otherwise it would seem that the whole organization was thoroughly immunized.

---

* From the Office of the Chief Surgeon, American Troops in England.

* Table 2, describing the salient clinical features of the forty cases of typhoid, is too large for publication in The Journal. It will be included in the authors' reprints.

[1] Official Weekly Bulletin 20.

CLINICAL FEATURES

Opportunity to make a clinical study of these cases was afforded one of us (C. B. H.) at Base Hospital 204, Hursley Park, Hants, through the kindness of Major J. B. Fattic, M.C., in command.

Prompt segregation of the patients was effected by screening their ward. Disinfection of excreta was accomplished by chemical means, all dishes, bed pans and urinals were scalded immediately after use, and no case of typhoid developed as a result of hospital infection. The diet was largely liquid. A plentiful supply of excellent milk and eggs was available, and was supplemented by broths, cocoa and soft foods, as much as possible, especially in the milder cases. Facilities for the preparation of articles of soft diet were limited, and consequently additions of this nature to the diet were not so extensive as might have been desired. However, the size of the intestinal ulcerations found at necropsy in the fatal cases was such as to cause extreme hesitation in the matter of more liberal feeding for the rest of the patients.

* In this table × indicates *cases in which B. typhosus* has been isolated, and + indicates cases which were clinically typhoid, but in which no B. typhosus has been *isolated to date.*

Table 2 has been prepared so that the salient features of this group of cases may be presented in as brief a form as possible. A short discussion and explanation of this table may aid in a clear understanding of the cases. Of the forty cases in the group, only two were clinically not typhoid. These are Cases 7 and 38.

1. Under the heading "Onset," the date and initial symptoms are shown. The establishment of the exact date was very difficult, and in many cases was determined by the clinical record during the course of illness at the hospital, verified as far as possible by a more or less indefinite statement of the patient. The striking feature shown under "Initial Symptoms," which are mentioned in the order of their occurrence, is the frequency of chill as the first abnormality noted by the patient. This occurred in approximately 16 per cent. of the cases, and was, by the patients' statements, a definite rigor. Diarrhea early in the onset occurred in approximately 58 per cent. of the cases, constipation in approximately 21 per cent., abdominal pain in approximately 6 per cent., and nosebleed in but one case, approximately 2.6 per cent.

2. The figures in the column "Duration on Admission" are based on the dates of onset, and are therefore not exact, but closely approximate the truth. The shortest duration of disease on admission was three days, the longest thirty-one days. From this column the average duration of disease on admission is determined as thirteen and one-half days.

3. Diarrhea was troublesome in but seven cases, constipation in six cases, abdominal distention in nine cases, and marked persistent abdominal distress in three cases.

4. Rose spots were observed in nineteen cases. Probable enlargement of the spleen as determined by percussion was noted in eighteen cases, and is designated by a single plus under the column marked "Spleen." Palpable spleen was made out in fifteen cases, and is shown in this column by a double plus. Tender toes, designated by a plus sign, were demonstrated in fifteen cases. In five cases this condition was so marked as to cause considerable discomfort.

5. The leukocyte counts are quite typical of typhoid. A count of 7,000 or less occurred in eighteen cases. The second count in Case 29 shows the leukocytosis of a complicating lobar pneumonia. The second and third counts in Case 33 show the leukocytosis of perforation and beginning peritonitis. The second count in Case 36 was considered as strong indication of perforation, occurring in coincidence with severe abdominal pain. However, there was not enough evidence to warrant operation, and we were later forced to conclude that the perforation, if any had occurred, had been sealed immediately by the omentum.

6. The results obtained by the atropin test are of extreme interest and worthy of a more extensive discussion than can be given in this report. In one column appears the day of disease on which the test was performed; in the next column is noted the pulse reaction. If an acceleration in pulse rate occurred, it is shown by a plus sign and a number representing the amount of increase due to the atropin over the normal rate immediately before the administration of atropin. Unfortunately, it was impossible to repeat tests in any of the cases because of lack of time. Two of the forty patients in this group, 34 and 37, died before the series of tests was started. Two of the remaining thirty-eight patients, 7 and 38, clinically not typhoid, showed accelerations of 24 and 34 beats, respectively, and should be considered negative reactions (acceleration of over 15 beats), leaving tests in thirty-six cases of clinical typhoid for consideration.

An acceleration of pulse rate occurred in thirty-three cases, a decrease of rate occurred in one, Case 33. No alteration in rate occurred in two, Cases 10 and 28. Twenty-three of the thirty-six cases showed a positive reaction (either a decrease, no alteration, or an increase of less than fifteen beats). The earliest day on which the test was performed in this group of twenty-three was the seventeenth day; the latest, the thirty-first day. The results in this group of thirty-six show a positive reaction in 63.8 per cent. of the cases. Of the eleven cases showing an acceleration of fifteen or more beats, the test was performed later than the thirtieth day of disease in seven cases, and in none was the test made earlier than the twenty-first day. It is only fair to the originators of this test to state that accuracy is not claimed for tests done later than the thirtieth day, and to point out the fact that if we eliminate the seven cases just mentioned, the percentage of positive results in the whole series of thirty-six cases would be 79.3 per cent.[2]

7. Typhoid bacilli were isolated from the blood in twelve cases, and from the stools in nine cases. In one, Case 34, the blood culture was positive as late as the twentieth day of the disease. In the column marked "Widals" are placed the results as determined by a series of tests made in each case.

8. The clinical course is briefly shown in the latter part of the chart. Average temperature and pulse rates, during the fastidium, are shown in their proper columns. The average

---

[2] These tests were carried out according to the technic described by Capt. H. F. Marris, R. A. M. C. (Brit. M. J. 2:717, 1916) and Special Report Series, No. 9, Medical Research Committee, to which article and articles on the same subject by Alfred Friedlander and C. P. McCord (J. A. M. A. 70:1435 [May 18] 1918) and E. H. Mason (Arch. Int. Med. 21:1 [Jan.] 1918) the reader is referred for further information.

duration of fever in thirty-two cases in which the patients are now convalescent is over thirty-five days. The shortest, Case 32, is nineteen days, the longest, Case 40, is fifty-eight days. Of the fatal cases, Patient 11 died the thirty-third day of terminal pneumonia; Patient 30 died the thirty-ninth day of toxemia; Patient 33 died the thirty-eighth day of surgical shock, following operation for perforation; Patient 34 died the twenty-seventh day of toxemia; Patient 37 died the ninth day of toxemia. Out of the thirty-eight cases, twenty-seven were high grade typhoids, much more severe than should be expected in vaccinated men. This is undoubtedly due to the average lateness in the course on admission to the hospital. The remaining eleven cases were mild, low grade typhoids. Complications occurring in this series were: Lobar pneumonia, one, Case 29; terminal pneumonia, one, Case 30; bronchopneumonia, two, Cases 11 and 30; severe bronchitis, six, Cases 1, 3, 8, 12, 27 and 34; hemorrhage, three, Cases 10, 12 and 13; perforation, one, Case 33; phlebitis, one, Case 36; bed sore, two, Cases 5 and 10; one, Case 15, is still febrile in the fifty-first day of disease.

TABLE 3.—SUMMARY OF LABORATORY FINDINGS

	No. of Cases
B. typhosus isolated from blood and from stool	4
B. typhosus isolated from blood only	8
B. typhosus isolated from stool only	5
Typical typhoid lesions at necropsy in cases in which the bacillus was not isolated during life (B. typhosus isolated postmortem from two of the foregoing)	3
Typical shift in typhoid agglutinins; blood and stool cultures negative	6

LABORATORY FINDINGS

Of the forty patients in this series, admitted to Base Hospital 204 as typhoid suspects, the laboratory findings were positive in twenty-six. The results are summarized in Table 3.

BLOOD CULTURES

Blood cultures in sterile oxbile yielded positive results in about 30 per cent. of the cases. This is higher than would be expected when it is considered that most were cultivated in the third week or even later in the disease. Moreover, it can be seen at a glance at Table 4, in which the cases are arranged in order of the date of onset, that the positive blood cultures are not grouped at the end of the table, among

* Units are determined by dividing the denominator of the fraction which expresses the highest dilution in which agglutination occurs by the correction factor. In this case the factor for typhoid suspension used was 7; for paratyphoid B, 4, and for paratyphoid A, 5, 4 or 5, according to the suspension used.

† In this column, T indicates typhoid vaccine; P, paratyphoid vaccine; TAB, triple vaccine; ? indicates vaccination not entered on service record.

‡ The place of vaccination and number of doses administered are taken from patients' statements, and the figures given are only approximate.

the cases tested early in their course, but are scattered through the list without obvious relationship to the stage of the disease at which they were made. A point that may explain these late positive cultures was very striking when the cultures were made. Blood was taken from ten of the patients the evening they were admitted to the hospital. Of these ten, eight were positive. Of twenty-nine cultures taken after the patients had been in bed twenty-four hours or longer, only four were positive. This at once suggests the possibility that the physical strain these febrile men had undergone was responsible for their persistent bacteremia.

Stool Cultures.[3]—The small number of positive stool cultures obtained was also surprising. The specimens were plated both on Endo and on Krumwiede's brilliant green, and the greatest care was used in studying the colonies. Nevertheless, only about 23 per cent. were positive even on repeated examination.

Agglutinin Reactions.[3]—The serum agglutinins of these patients were studied by the method of Dreyer.[4] In this we were greatly assisted by Dr. A. D. Gardner, of the Standards Laboratories, Oxford, who supplied us with standardized suspensions. The results, which are summarized in Table 4, are interesting from several points of view.

From the diagnostic standpoint these reactions gave us evidence of typhoid infection in a number of cases, typical clinically, in which all cultures were negative. This includes one case (25, Table 4) which was febrile during the patient's stay in the hospital and in which there were no signs or symptoms suggesting typhoid, although the patient gave an indefinite history of illness while at sea. On the other hand, in some cases in which the tests were made at too long intervals there were variations in the agglutinins for paratyphoid A and B, which might have been interpreted as evidence of infection with one of the organisms, although on epidemiologic evidence such a diagnosis can almost be excluded. The result, however, shows the necessity of caution in interpreting results of agglutinin titrations, especially when observations at intervals of a few days during the third and fourth weeks are not made.

---

[3] The majority of the stool examinations were made by Dr. T. L. Harkey, and the agglutinin titrations by Miss M. Vaughan.

[4] Dreyer: J. Path. & Bacteriol. 13: 332, 1909.

POSTMORTEM FINDINGS

Necropsies were performed in the five fatal cases in the series. All showed typical typhoid ulceration of the lower ileum. A very striking feature was the enormous enlargement of the spleen in the first two cases, in one of which the patient died early in the disease (twelfth day). In both these cases the spleen weighed over 500 gm., was very firm, and the pulp on section rather dry; the spleen wholly unlike the typical soft spleen of typhoid.

In the first case, in which the patient died on the twelfth day, the Peyer's patches were in the stage of medullary swelling. In the second case (thirty-second day) there were large, deep ulcerations with hemorrhage into the bowel. In the third case (thirty-seventh day) also there were deep ulcers, one of which had perforated and caused a local peritonitis. The two remaining patients, who died on the thirty-fourth and thirty-sixth days, showed ulcers in the stage of repair. One died of bilateral lobar pneumonia, with empyema, due to Pneumococcus Type I. In the fifth case new lymph follicles had become involved and were in the stage of medullary swelling — evidently a recrudescence. The fifth patient had an intramuscular hematoma of the rectus abdominalis. The first and fourth cases showed thrombosis and infarction of the lung. In the fourth, the infarct was surrounded by a large area of lobar pneumonia. No other complicating lesions were observed.

In the first two cases, typhoid bacilli were isolated from the spleen. Cultures from the third case were heavily overgrown with colon bacilli, and *B. typhosus* was not recovered. In the fourth and fifth cases, cultures from the spleen were negative, but the typhoid bacillus was found in the gallbladder.

COMMENT

The most interesting question that arises in regard to these cases is: Why did this large group of vaccinated men become infected? To this, three possible answers present themselves: First, that the vaccination was defective; second, that the infection was due to the abnormal race of *B. typhosus* against which the vaccine did not protect; third, that the men received an overwhelming dose of the infecting organism.

The first hypothesis seems improbable from the fact that the men were vaccinated at different camps and at different times, so that it is hardly possible that all received the same batch of vaccine. Additional evidence on this point is seen in the record of their agglutinins for paratyphoid A and B (Table 4). When first examined, the majority had from 25 to 100 agglutinin units for these organisms in their serums. This means agglutination in dilutions from 1:100 to 1:500. It is no lower than frequently found in healthy soldiers from eight to twelve months after vaccination, and shows that the vaccine was good and that the men reacted to it. It is true that a few men in the series had a very small amount of agglutinin or none at all for these organisms, even when their records stated that they had received triple vaccine; but this fact could not explain the majority of the infections.

It might be suggested that the paratyphoid agglutinins that were observed in these cases were group agglutinins, due to the typhoid infection and not to the paratyphoid vaccination. It has been the experience of Dreyer and his co-workers that group agglutinins of this sort are not encountered.[5] Moreover, it was readily shown in cases that were tested by absorption that the three agglutinins were distinct. The possibility that these infections were due to defective vaccine can, then, practically be excluded.

As to the second hypothesis, that the infections were due to an abnormal strain of typhoid, we have no positive evidence. All the strains isolated gave characteristic fermentation results on glucose, lactose, mannite and saccharose; and all with one exception agglutinated in typhoid immune serum in about the same dilution as the homologous strain. One strain isolated from the blood (24, Table 4) has remained inagglutinable so far, although its cultural reactions are typical.

It has been shown by Weiss[6] that minor differences both antigenic and cultural can be brought out between certain races of *B. typhosus*. We propose to investigate these strains further in this respect.

In the absence of evidence that the prophylactic immunization of these men differed in any way from that which has, in the vast majority of cases, given adequate protection, or that the strain of typhoid with which they were infected was atypical, there remains the hypothesis that they received an excessive dose of typhoid bacilli.

CONCLUSIONS

1. Owing to the lateness in the course on admission to hospital, cultural confirmation of clinical diagnosis was impossible in a considerable number of cases. The fact that all of these men had received routine immunizing vaccine during the past eleven months made the ordinary Widal reaction unreliable. Careful clinical study, however, justifies a positive diagnosis in thirty-eight of the cases.

2. That severe typhoid may occur in vaccinated men is proved by this series of cases.

3. The occurrence of uniformly low white blood counts in this series again illustrates the diagnostic value of routine blood examination in all febrile conditions.

4. It is felt that the atropin test may be of great value in the diagnosis of typhoid fever, although the smallness of this series, the impossibility of laboratory confirmation of diagnosis, and the lack of control cases makes authoritative conclusions in this matter impossible.

5. It is hoped that the explanation of the lamentably high mortality rate (13.15 per cent.) may be found in the average lateness in the course of disease on admission to the hospital.

Checking the Senses.—Bear in mind that each of you, the field commander of your own life's warfare, lives in a dugout. You are helpless except for your lines of communication, your senses. Guard them as a most precious possession. Train them to do their work well; watch them; suspect them. Send your eyes to spy on your ears. Bring up smell to reinforce vision. Suspect the message and send the messenger back again to examine, and again to reexamine, until you are sure the news is true; sure that the valvular sound is such and no other; sure that the reflex is absent; sure that the urine contains albumin; sure beyond a doubt of the thousand items of sense information that come to your headquarters and are needed in your business—the warfare on disease.—E. P. Lyon, *Texas State Journal of Medicine.*

THE EARLY DIAGNOSIS OF GAS GANGRENE

FREDERICK CHRISTOPHER, M.D. (Chicago)
First Lieutenant, M. C., U. S. Army
FRANCE

The literature on the subject of gas gangrene is already so voluminous and so comprehensive that any one attempting to contribute further to it must have a very good reason for doing so. With our present methods of treatment, however, the early clinical recognition of this condition is of such outstanding importance to the good of the wounded men that it has seemed that undue emphasis cannot be placed on it.

Conditions of war surgery are such that the men who operate on the patients are seldom able to make the dressings. The first dressings are often made in different hospitals from those in which the patient was operated on. When the patient is first brought up for operation, gas gangrene may already be present, or it may develop after the operation. In the latter case, the responsibility for the early recognition of gas bacillus infection rests practically entirely on the shoulders of the men who make the dressings.

Examination of the statistics of the causes of death of patients in American Paris hospitals during a recent drive afforded very convincing evidence of the menace of gas gangrene. In the protocols of 100 consecutive necropsies performed by Major H. E. Robertson, M. R. C., I noted that in 33 per cent. of the cases the probable cause of death was the injury plus gas gangrene, and in 8 per cent., the injury plus gas gangrene plus other causes, as pleuritis or hemorrhage. In a large group of these cases, the diagnosis was made too late to be of any service to the surgeon.

Many writers have described various forms of gas gangrene. Weinberg and Seguin[1] distinguish (*a*) the classical or emphysematous form; (*b*) the toxic, or edematous, form; (*c*) the mixed form, and (*d*) the putrid varieties. They have cultivated numerous organisms from gas gangrene cases, but believe that the leading rôles are played by (*a*) *B. perfringens* (*B. aerogenes-capsulatus* of Welch); (*b*) *B. oedematiens*, and (*c*) *vibrion septique*. As one or another of these micro-organisms predominates, correspondingly, certain sets of symptoms seem to be more evident. From the standpoint of the clinician, who is eager to learn the best means of arriving at an early diagnosis, it seems safest to consider gas gangrene as a clinical entity of multiple etiology and one in which the most striking sign or symptom is not always the same in all cases.

Taylor[2] has classified the various stages in the course of gas gangrene as: (1) dormant stage; (2) stage of acute gaseous distention; (3) explosive stage; (4) stage of systemic intoxication, and (5) stage of septicemia. It is in accordance with my purpose in this paper to omit all discussion of the first, third, fourth and fifth of these stages, and the etiology, bacteriology, pathology and treatment as well, and to confine the study to the consideration of the best methods of recognizing the stage of acute gaseous distention, particularly in postoperative wounds. If the infection is recognized in this second stage, it is generally possible to forestall its progress to later stages by prompt and adequate surgical treatment. If the disease has reached the third or succeeding stages without operation, the diagnosis offers little difficulty.

FACTORS TO BE CONSIDERED IN ARRIVING AT AN EARLY DIAGNOSIS

1. *The Patient's Chief Complaint.*—The patient may have no complaint. Pain in the region of the wound, however, is a very common complaint and one that should always command attention. Taylor believes that pain of short duration followed by numbness is characteristic. The Chaliers[3] refer to the frequency with which patients ask to have their bandages loosened. Pain in the limb distal to the wound has been mentioned.[4]

2. *History.*—The length of time after the receipt of the injury is of first importance. All wounds are to be suspected and watched for a period of from six to eight days. Wounds are not immune from gas bacillus infection after that time, as is shown by the interesting case of Penhallow[5] in which, though the wound had healed and the operation was performed two months after the injury, it stirred up a latent gas infection. The patient may know whether the missile which struck him was a machine gun bullet or a fragment of shell. A history of previous operation or operations may be elicited, and if these have been performed, the time interval between the injury and the first operation should be learned.

3. *The General Condition of the Patient.*—Generally the euphoria and maintenance of intelligence is very striking, which is in accord with the observations of Chalier and Chalier.[3] We cannot agree with one author[4] that drowsiness is a marked symptom. Albrecht[6] notes restlessness.

The temperature is not characteristic, though it may be elevated. Speed[7] considers the lack of high fever of importance. Col. Joseph A. Blake calls attention to the frequency with which low temperatures are found.

The pulse is very important, for it is almost invariably increased in frequency. It is of great help to the surgeon to have the pulse rate curve placed on the bedside chart along with the temperature curve. A high elevation of the pulse rate without corresponding increase in the temperature should attract the surgeon's attention. Colonel Blake considers the crossing of the pulse and temperature curves very characteristic.

The respirations are generally more rapid, though "dyspnea has a greater prognostic significance than diagnostic value."[3]

The tongue is commonly dry. Vomiting has been observed,[8] but is uncommon.

4. *Inspection.*—The type of wound is of first importance. Gas gangrene is essentially a disease of traumatized muscle (Taylor) and consequently is most frequently found when the wounds are in the large muscle masses. The thigh, the shoulder muscles and the calf are frequent sites of election. Wounds made by shell fragments with the foreign body still buried in the

tissue are almost certain to be infected with one or more of the causative agents of gas gangrene. Even apparently clean, through-and-through machine gun bullet injuries with sealed wounds of exit and entrance may develop gas gangrene. While gutter wounds are perhaps among the safest, if there is obvious dead muscle tissue present, they too are to be suspected. Wounds that have undergone no surgical treatment are very liable to develop gas gangrene, owing to the presence, along the missile tract, of masses of traumatized and necrotic muscle, which is very favorable to the growth of the gas bacillus and other etiologic agents. Wounds that are widely opened and debrided are unfavorable to the growth of anaerobes, to which class most of the organisms of gas gangrene belong. Poor gas drainage is responsible for the spread of the gas in the muscle bundles, and in consequence is in a large measure responsible for the spread of the infection itself.[9] As gas drainage is generally very adequate in open wounds, there is less chance of the extension of the infection in these cases. If the débris of the wound has already been removed, the extent of the operation must be judged to be ample or insufficient. "Wounds involving main blood vessels, for example, the popliteal artery, are notorious for the frequency with which gas gangrene develops in the distal segment of the limb."[10] In these cases the organisms of gas gangrene find an excellent medium for their growth in the muscles whose vitality has been diminished by the depletion of the blood supply.

The site of the suspected gas gangrene must be examined to see if it has been subjected to continuous pressure, as with the buttocks and back in many cases, for it is known that metastatic gas gangrene may develop in parts of the body widely distant from the wound, if these parts have an impaired circulation from pressure owing to failure to change the patient's position in bed from time to time.[11]

The most important single sign seems to be the swelling. It is invariably present. Any swelling about a recent battle or operative (war) wound should be considered to be due to gas gangrene unless it is proved to be otherwise. The swelling is often fusiform in shape on account of the fact that in the early stages the gas confines itself to the muscle bundles along which it travels longitudinally. It may affect an entire limb or it may be limited to one border of a wound. When there is a large open wound with good opportunity for gas drainage the tension will be less and the swelling smaller or perhaps purely local in character. Taylor has photographs of a case in which the gas has lifted up the fascia lata tensor to the level of the patella on the anterior surface of the thigh. It is only the smaller swellings that interest us in the early diagnosis; when the swelling is very large, the diagnosis has by that time generally been well established.

The color changes in the skin have been very carefully described by Col. Cuthbert Wallace.[12] He notes that at first the skin is paler than normal, owing to the blood's having been driven out of it by pressure. Then "a dirty cream tint gradually appears and may be taken as a sure sign that gangrene is established." Next, irregular purple areas which enlarge and coalesce appear. By this time blebs have formed, and the dermis under them is a shining purple-red. Finally, a yellowish green tint is seen. In some cases the whole body may have an icteric tinge. Emrys-Roberts and Cowell[8] find that "the sclerotics become distinctly icteric." In mixed infections the skin may be red, as in ordinary pyogenic infections. The erysipèle bronzé is occasionally seen.[13]

The increased visibility of the superficial veins has frequently been noticed in the neighborhood of gangrene.

In case a portion of muscle is exposed in the wound so that its color may be observed, the successive changes as the gangrene progresses are brick red, green and finally black.[12]

Taylor has called attention to the bulging of the muscles from the wound that is sometimes found with gas gangrene.

The discharge may be said to be characterized by a absence of suppuration. If the discharge is increased thin, and pale brown,[14] gas infection is to be suspected Sacquépée[13] finds that the discharge varies from red brown to violet.

Blebs on the skin occur so late in the course of th infection as to be unimportant in the making of a early diagnosis.

5. *Odor.*—The odor from a wound infected with ga gangrene is generally considered to be very characte istic, and various attempts have been made to descri it. Speed says that it is "fetid and extremely pen trating, resembling that from the thin stool of a infant suffering from extreme enteritis and acidosis The Chaliers,[3] however, consider the odor mouseli and say that it is neither putrid nor fecal. Taylor sa that the odor of butyric acid may be recognized in t odor of gas gangrene.

6. *Palpation.*—Crepitus has long been identified wi gas gangrene. When a limb whose tissues have be infiltrated with gas is gently palpated, a very defini fine crepitus may be elicited. This is an importa sign, but it is far from an infallible one. It is due the passage of gas bubbles through the foramina in t muscle sheaths. Kenneth Taylor and also Wallac contend that the muscles become resonant from t presence of gas long before they become crepitant the finger. Wallace says that crepitation does necessarily mean microbic infection and is a l phenomenon; and moreover, that it is not alw present with gas. The sensation of crepitation m also occur in fractures, following incorrect inject of serum; in the mechanical emphysema occurr sometimes in wounds of the limbs near flexion fol in laryngotracheal wounds; in chest wounds; in s cutaneous emphysema in intestinal wounds; in wou of the rectum with emphysema of the thigh; in he toma with gas; in plegmon gaseuse;[3] and Tuffi mentions certain gangrene in vascular lesions whic able momentarily to contain gas.

On palpation, the swelling frequently has an ela tense consistency which readily may be distinguis from the fluctuation of an abscess or the pitting edema.

Induration is not uncommon, and is particularl be found in those cases in which gas gangrene deve on the border of an open wound. It is probably n frequently found in cases in which the gas infec is complicated by the presence of pyogenic organisms.

[15] Wallace, Cuthbert: J. R. A. M. C. (May) 1917.

[16] Tuffier: Bull. et nérv. Soc. de chir. (Nov. 3) 1914.

Tenderness on palpation is generally present, but there is not the exquisite pain found in inflammations of a pyogenic nature, except, perhaps, in cases of mixed infections.

By pressure with the flat of the hand toward the wound edges, frequently small gas bubbles may be milked into the wound. When present, this is practically a sure sign of gas infection; but the process is generally fairly well advanced by the time it is demonstrable. Moreover, care must be taken not to mistake air, which may normally be present in the deep recesses of the wound and which may similarly be pressed out, for gas bubbles.

Edema may be present to a certain extent in some forms of the infection. According to many authors, it is due, when present, to *B. oedematiens* of Weinberg and Sequin. It may be present also in cases in which the pressure of the gas has caused venous obstruction.

The muscle, if present in the wound, may be tested for contractility by pinching with a forceps or for bleeding by scraping. If either of these signs is absent, it is tolerably safe to assume that the muscle is dead. Dead muscle, if gas infection is not already present in it, eagerly invites its development.

7. *Percussion.*—On percussion, a limb distended by gas infection gives a tympanitic note. This test is believed to be of considerable value in the early diagnosis.

8. *Auscultation.*—An early method of demonstrating crepitus is to press the bell of the stethescope on the affected limb; a crackling may be heard in this manner, before it can be palpated.

9. *Roentgenoscopy.*—Roentgenologic examination is a helpful means of arriving at an early diagnosis. Morgan and Vilvandre[17] have demonstrated the presence of gas entirely unsuspected until revealed by the rays during routine examinations for pieces of metal or fractures. The roentgenographic appearance of the gas is usually that of: (*a*) bubbles in strings; (*b*) broad cast; (*c*) in a layer under the skin; (*d*) with a cloudlike outline to the shadows, or (*e*) as a striation.[16] The bubbles need not be circular, but may fit the shape of the cavity they are in. Agnes Savill[18] is even so sanguine as to the power of the roentgen ray that she believes she can determine by it the variety of gas infection in some cases. Among the causes of failure that one must beware of in making a diagnosis of gas gangrene from the roentgenogram are: ecchymosis; syringing the wound with hydrogen peroxid; (25) shadows made by wounds; surgical emphysema; normal structures (popliteal space, bursae), and hematomas.

10. *Cultures.*—Culture of the wound is not of great value. Though the gas bacillus may generally be identified within eight hours by its growth on milk, the gangrene may spread rapidly within that time. A negative culture is of no value, and a positive culture is not infrequently found in wounds that are wide open and will never require further surgical intervention.

11. *Aspiration of Gas.*—Diagnostic aspiration of gas from muscle is occasionally of value in making a diagnosis.[2]

12. *Smears.*—Microscopic examination of smears made from the wound is of no value when negative and of but slight value when positive, for even then surgical therapy may not be indicated.

13. *Reaction.*—The reaction of the wound has been tested as an aid to diagnosis, for Sir Almroth Wright[19] showed that the organisms of gas infection tend to make acid the medium in which they grow; but little stress is to be placed on this test clinically.

REPORT OF CASES

The cases reported are of interest because of the problems of diagnosis that they offered.

Case 1.—Private C. C. C., aged 28, wounded, July 29, 1918, admitted to American Red Cross Military Hospital No. 2, July 30, had a gunshot wound, received in battle, in the middle of the right thigh, posteriorly. Gas infection was present. Roentgenoscopy revealed a foreign body measuring 30 by 40 mm. in the right buttock. July 30, the wound débris and the shell fragment were removed. Carrel-Dakin treatment was instituted. The condition of the wound seemed satisfactory until August 4 (six days after admission), when a small, indurated, red area on the upper border of the wound was noticed. The temperature was 103 F. and the pulse 70. No diagnosis of gas gangrene was made. August 7, the wound was examined and dressed under an anesthetic in the operating room, but the surgeon decided that no operation was necessary. August 9, gas bubbles could be pressed out of the wound. The temperature was 103.4 and the pulse 98. The patient was taken to the operating room and a very wide débridement was done. The patient recovered from the shock of operation only to go into a toxic state, and he died the following morning. This case is of interest for the fact that though the patient was carefully watched by several observers, the diagnosis of gas gangrene was not made until it was too late to save the man's life.

Case 2.—Private C. W., aged 22, wounded, Aug. 4, 1918, admitted to American Red Cross Military Hospital No. 2, August 8, had received a through-and-through gunshot wound of the left thigh and left foot. The wounds were probably due to machine gun bullets. There was a marked hematoma of the left thigh. Roentgenoscopy was negative for a foreign body and the patient was sent to the ward for observation. August 11 (three days after admission and six days after the injury), the patient complained of pain in the thigh. The temperature was 100.4 and the pulse 120. Roentgenoscopy showed that the muscles of the thigh were spread apart and that there were light spaces in between them. It seemed probable that there was a gas bacillus infection. There was, however, a large hematoma. Numerous Carrel tubes were placed. The temperature gradually came down to normal after a week, and recovery seems assured today (Aug. 21, 1918). This case is of interest because the hematoma produced the roentgenographic appearance of gas in the muscle, and because, though diagnosis was not assured, decision to operate was made. There can be no regrets on failure to find gas in a suspected case, and the surgeon's course here seems to be entirely justified.

CONCLUSIONS

1. There is no single early pathognomonic clinical sign or symptom of gas gangrene. The condition is a syndrome, and the diagnosis generally depends on the combined presence of several signs or symptoms.

2. For an early diagnosis of gas gangrene, the more reliable factors are: history of a recent wound; swelling; increased frequency of pulse rate; tympany; crepitus (auscultatory and palpatory); pale color of skin; odor; ability to milk gas bubbles out of wound; thin discharge; roentgenographic findings, and maintained intelligence of the patient.

3. It is to be recommended that all swellings about wounds be considered as due to gas gangrene until proved to be otherwise. In cases of doubt, the wounds

must be reinspected at intervals of not greater than two or three hours, or even subjected to surgical exploration. The responsibility of the early recognition of gas bacillus infection rests practically entirely on the shoulders of the men who dress the wounds. All roentgen-ray men who do not already do so should look for evidences of gas infection in every examination of war injuries made within ten days after the receipt of the wound.

RECONSTRUCTIVE SURGERY

THE PROBLEM OF RECORDS *

J. APPLETON NUTTER, M.D.
Assistant Orthopedic Surgeon, Clinic for Functional Reeducation
NEW YORK

In the treatment of diseases and disabilities of the joints there has always existed the difficulty of making suitable records. The difficulty has been one not only of accuracy, but also, to a much greater extent, of clearness and intelligibility. Where one surgeon, referring to movement at the shoulder joint, speaks of abduction of the arm, another speaks of elevation of the arm, and a third of side raising.

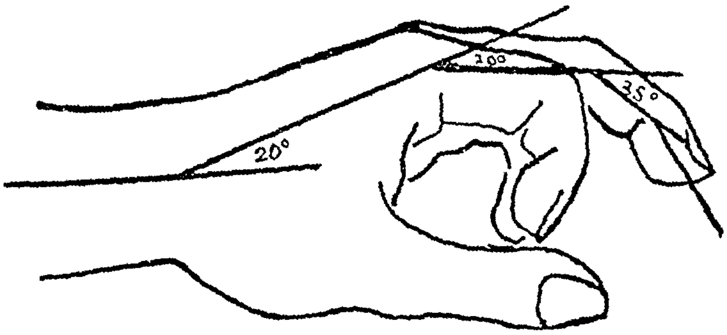

Fig. 1.—A stiff middle finger of the left hand that *cannot* be flexed voluntarily more than is shown. How can we record rapidly, accurately and intelligibly its position of deformity as well as range of motion? This is absolutely necessary so that improvement *or* its absence can be noted. The first step is to be able to record every possible position of the finger, as in this way we can note how far it flexes voluntarily, and how much more flexion can be gained by force: the *same* two points to be noted as regards its power of extension.

In the case of a stiff knee, almost hopeless confusion may exist in its actual description. One surgeon in his case report will speak of a straight leg as being fully extended, while a confrère will likely refer to it as showing 180 degrees extension.

These difficulties reached a climax when in Canada the board of pension commissioners at Ottawa was inundated with thousands of reports on joint disability and deformity, made by thousands of different army surgeons. Their descriptions depended almost wholly on words for accuracy, and were seldom aided by diagrams. Though they were correspondingly difficult to interpret, nevertheless on the accuracy of their interpretation by the pension commissioner depended the fairness of the pension adjustment. The government in self defense thereupon caused to be printed a series of charts showing the extremities, with the range of motion marked in degrees, and required these to be filled in by the examining surgeons. These charts worked well as far as the larger joints (knee and elbow) were concerned, but in the case of the hand they were not so successful.

In Hart House, Toronto, where some of the most advanced work in physiotherapy has been done on this side of the water, the relative position of one bone to another at a joint, as well as joint movement itself, is very accurately recorded on charts, one of which is reproduced in the accompanying table. These charts are arranged to accommodate practically every joint in the body, and show not only degrees of motion, active or passive, but also the strength of movement. These charts, needless to say, were meant to be used in conjunction with Prof. E. A. Bott's splendid series of mechanotherapy apparatus. Each machine has a dial by which its motion (active and passive) can be measured accurately in degrees. By using the Bott machines and recording the results on the charts provided for the purpose, the workers in the mechanotherapy room at Hart House were able to furnish themselves with a splendidly accurate record of joint deformity and motion which marked a great step forward in the scientific treatment of the surgery of the extremities.

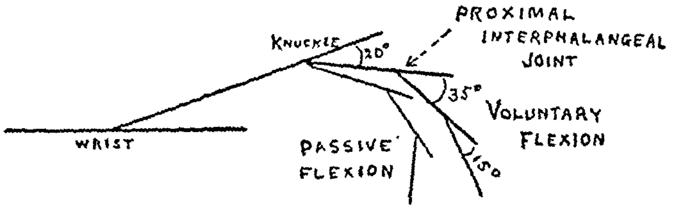

Fig. 2.—Flexion record of left middle finger, same case as recorded on Hart House chart. We are marking these angles in degrees for the sake of clearness. It will be noted that the lines represent the axes of the phalanges and metacarpal bones. No account is taken of the carpal movements, but only of the wrist as a whole.

Strength of motion at the various joints was estimated and recorded in percentages, the sound side being reckoned as 100 per cent. strong. No attempt was made in estimating strength to use a dynanometer or to calculate foot pounds, as it has been found that such methods were too elaborate for a busy clinic. The workers were trained to estimate the strength of a certain movement as compared with that of the corresponding movement on the opposite side.

When the Clinic for Functional Reeducation was opened in July, 1918, it had already had the benefit of a visit from Professor Bott, whose collaboration was greatly appreciated. The measures in use at Hart House at that time showed the high water mark of scientific efficiency and accuracy, and an opportunity was taken by several of those connected with the clinic to study them during a stay in Toronto.

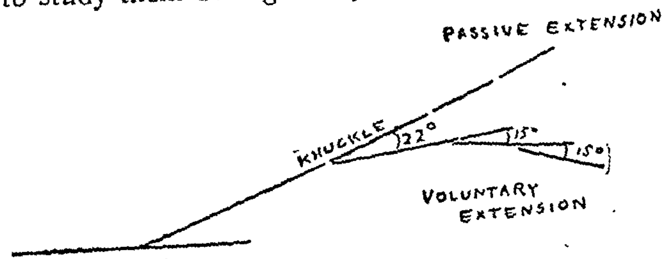

Fig. 3.—Extension of left middle finger.

The mechanotherapy room at the Clinic for Functional Reeducation is equipped with apparatus from two main sources, and to Major Tait McKenzie, R. A. M. C., professor of physiotherapy at the University of Pennsylvania, we are chiefly indebted for encouragement and assistance. As the work grew in volume it was noted that, especially in hand and finger cases, accurate tabulation of deformity and motion on the charts meant a somewhat tedious undertaking. The results also, while undeniably accurate,

---

11. Tay
12. Walt the Clinic for Functional Reeducation.

were also rather unintelligible. In an effort to remedy the multiplicity of findings, recourse was had to diagrammatic drawings representing the hand and fingers. These drawings were made free hand, and in them a single line or succession of lines represented forearm, wrist, and each of the three phalanges. They were used in conjunction with the Hart House charts and had the advantage that they showed at a glance the position of the various joints of wrist and fingers. No attempt was made to record strength of movement graphically, but active and passive motion, whether in flexion or extension, was shown on the diagram.

HART HOUSE CHART

Middle Finger (Left)	Movement Active	Passive
Prox. flex.	20°	35°
Ext.	Lacks 5° of full	Full
Med. flex.	40°	45°
Ext.	Lacks 20° of full	Full
Dist. flex.	20°	45°
Ext.	Lacks 30° of full	Full

This is quite an accurate record of the finger, but takes a very long time to estimate and put down, and equally long to get a connected idea from reading it.

We have so far found the graphic method of such benefit to us in our hand cases that its use is now gradually extending to the larger joints.

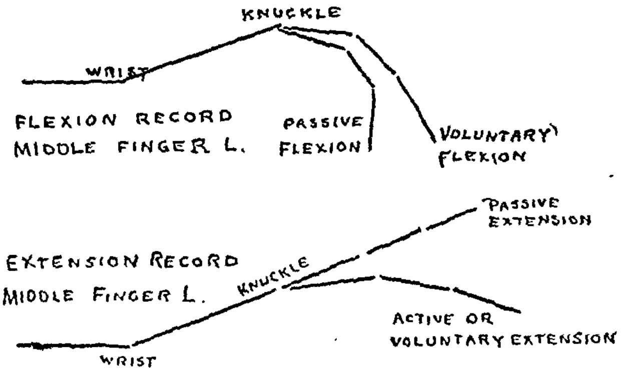

Fig. 4.—Graphic records, simplified and as in actual use. These take very little time to sketch free hand. If actual measurement in degrees of a joint is wanted, the sketch is used and the angles are measured

A few illustrations are appended of the graphic methods as used at the Clinic for Functional Reeducation in the hope that reconstructive surgery in general and the work of the War Risk Insurance Bureau in particular may be lightened.

5 Livingston Place, Stuyvesant Square.

Platinum.—In an article on platinum in *Commerce Reports* it is said that previous to the war 90 per cent. of the world's output of platinum was produced in Russia. The Russian field and the newer and less developed field in Colombia, South America, constitute the world's two important sources of this valuable metal. Notwithstanding the great demand for the metal in carrying on important processes during the war, the production in Russia fell off from about 300,000 ounces in 1911, to about 78,000 ounces in 1916. To counteract this in part, production in the Choco district of Colombia increased from 12,000 ounces in 1911 to about 50,000 troy ounces in 1917, an increase of 300 per cent. in this practically new field. In addition to the usual employment of platinum in electrical apparatus, crucibles, etc., the requirements were greatly increased during the war on account of the greatly enhanced needs for internal combustion engines for airplanes, automobiles, tanks and motor boats, the manufacture of fuming sulphuric acid, in which platinum is employed as a catalyzer or changer, important in munitions manufacture, and in the manufacture of nitrogen from the air, also required for explosives.

Clinical Notes, Suggestions, and New Instruments

HERNIA THROUGH THE FORAMEN OF WINSLOW: REPORT OF A CASE

J. E. Engstad, M.D., Grand Forks, N. D.

H. B. was referred to me by Dr. Knutson of Buxton, N. D., and admitted to St. Michael's Hospital in this city, about midnight, August 3, suffering from intense pain in the epigastric region.

The patient gave a history of sudden attack of pain while lifting a heavy object about twelve hours before admittance. The family physician was called, who immediately recognized the gravity of the case and ordered the patient sent to the nearest hospital. The journey of more than 20 miles was accomplished in an automobile improvised as an ambulance.

The abdomen was very rigid and sensitive to pressure, and a tense mass was felt in the right epigastric region. The pulse was about 36, heart beats 90, the organ being in a state of auricular fibrillation, and temperature, 103. The kidneys and lungs were normal. After a speedy preparation a long incision was made, and immediately there protruded large masses of dilated and congested intestine filled with fecal accumulation.

The strangulated intestine was soon recognized as being a part of the upper portion of the jejunum, about 75 cm. from the fossa of Treitz, the strangulated portion being caught in the foramen of Winslow. Traction was first made to relieve the impacted intestine, but the strangulated loop had already become edematous, and it was found necessary to introduce the tip of the index finger into the tight opening, carefully severing first the peritoneal covering and gradually the connective tissue of the opening, extreme care being exercised not to injure the immediately overlying structures, the portal vein or the common duct. All the structures underlying these canals had to be cut before the impacted loop could be released, the latter being accomplished by application of moderate traction.

The loop was immediately covered with warm packs; the intestine was then opened and emptied of pancreatic fluid and bile, after which the opening was closed by the usual intestinal sutures, silk and catgut being used.

The injured intestinal tract at once showed unmistakable signs of restored circulation. The operation was completed by the introduction of two small drains and the usual closure.

No effort was made to close the large foraminal opening, this omission being based on, first, the supposition that an enlarged opening would not again implant any loop of the intestine that might be forced into the cavity, and, secondly, the great danger of traumatizing the vein.

The drains were removed the second day.

The patient rallied immediately, and the progress toward recovery was rapid and without any incident up to the tenth day, when, without any previous warning, there was a rise in the temperature, the wound opened up, and a profuse serous discharge appeared. This rapidly changed in character, at times to bile and pancreatic fluid. The fat underlying the skin rapidly sloughed away, and on the whole the case looked rather unfavorable. On the thirteenth day an orange seed appeared in the discharges, which immediately relieved our misgivings, for instead of a fistula of the common duct, we now knew that we had a small intestinal leakage from the drainage incision in the intestine, which was about 40 cm. from the duodenojejunal fossa, or 60 cm. from the ampulla of Vater. The secretions from the fistula appeared at times almost unchanged bile and pancreatic fluids.

In due time the opening was packed, which controlled the discharge of the secretions, and the wound healed rapidly. The patient was discharged from the hospital five weeks after the operation, with good health, the wound being healed with the exception of a space about an inch square, filled with granulation tissue.

COMMENT

The large death rate from operative procedure for hernia into the foramen of Winslow is due, no doubt, in a great measure to the constriction of the intestine in its most vital portion, the so-called medulla oblongata of the intestinal tract, where are located the secreting glands of the upper bowel, whose functions are to supply the still partially mystifying hormones, whose reabsorption is speedily followed by death.

Bile and pancreatic fluid are constantly pouring into the distended intestine, adding their quota to the rapidly accumulating deadly contents of the dilated intestine.

The vital point of any operation for the relief of accumulation in this part of the intestinal tract is the mechanical emptying of all accumulated fluids by a large transverse incision in the intestine at a point midway between the normal portions. The emptying should be performed by gentle milking; otherwise the traumatized blood vessels might become injured and emboli might rapidly form in the mesentery veins or arteries, which, of course, is concomitant with death of a segment of the bowel.

Whether the introduction of the drains predisposed to the fistula is a problematic question.

REPORT OF CASE OF FAT EMBOLISM

R. M. Harbin, M.D., Rome, Ga.

History.—A married woman, aged 56, rather compact and stoutly built, sextipara, weighing 150 pounds, had had normal health in every respect until two years before admittance to the hospital, when she suffered an attack of appendicitis which passed off in three or four days. Aug. 12, 1918, there occurred a more severe attack in which the bowels had been made to move with difficulty. Two months later there was another attack with diarrhea, and subsequent difficulty was experienced in moving the bowels. This attack passed off in ten days, leaving tenderness diffused over the right abdomen. This persisted until the attending physician advised the patient to enter the hospital, November 15.

Examination.—The heart and lungs were normal, and blood count revealed: red cells, 3,860,000; white cells, 7,400; hemoglobin, 80 per cent.; polymorphonuclears, 63 per cent.; large lymphocytes, 3 per cent.; eosinophils, 1 per cent; small lymphocytes, 32 per cent. Urine and feces were negative. Palpation revealed a diffuse induration in the right lower quadrant. The barium-buttermilk meal revealed normal size and motility of stomach and delayed passage at ileocecal valve, and then stagnated at the caput coli at forty-eight hours. A colon injection of barium-buttermilk joined this delayed bolus.

Operation and Result.—A diagnosis of intestinal obstruction from adhesive remains of a previous peritonitis was made, and laparotomy advised and executed. After morphin-gas-ether anesthesia, through a 6 inch right rectus incision there was revealed a diffuse matting of coils of the lower ileum about the ileocecal junction. The operation was tedious, and the manipulations were severe, lasting two and one-half hours. The remains of the appendix lay buried in dense adhesions in the right iliac fossa. In the dissection of these bands of adhesions, quite a portion of the parietal peritoneum was destroyed, and it was found impossible to cover the denuded area.

Apparently the patient stood the operation well, reacting to consciousness promptly, and all the time retaining a pinkish color. Just before operation the pulse was 84 and temperature 97, and she left the operating table with a pulse of 98, which remained unchanged for seven hours, when it rose to 106 and then to 124. She had had two doses of morphin, one-eighth grain each. She became restless, with occasional vomiting. One quart of saline infusion had been given by rectum. Twelve hours after operation she complained of air hunger, yet the skin remained somewhat pinkish. The pulse was imperceptible at the wrist, and the heart sounds seemed frictioned and souffled. As we feared a concealed hemorrhage, the incision was opened after nitrous oxid-oxygen anesthesia, which was preceded by one-fourth grain of morphin and 1/150 grain of atropin. The peritoneum was tense and, when opened, about 100 c.c. of a soupy fluid escaped from tension. The patient died twenty-four hours after operation.

Necropsy.—The incision was opened, and 30 c.c. of fluid, aspirated from the pelvis, showed globules of fat. The left ventricle was tapped, and 50 c.c. of blood had the appearance of dark reddish orange juice. This specimen within ten minutes formed a firm coagulum quite the size of the original quantity of blood. This specimen was beaten up and washed with ether, which was then evaporated. The residue, on being stained with sudan III, showed fat. The peritoneal fluid was treated in the same way and showed quantities of fat.

INTRAPERITONEAL ABSCESS CONTAINING ROUNDWORMS

F. H. Jackson, M.D., Houlton, Maine

This case is reported because of its rarity. In the surgical literature cases have been reported in which the ascaris has entered the larynx and various portions of the hepatic system. Intestinal obstruction has been caused by masses of the parasite, and other cases similar to this one have been reported.

History.—B. B., a girl, aged 16, was admitted to the Madigan Memorial Hospital under my care, April 27, 1917. She had been operated on in the same institution, Jan. 20, 1916, for an intraperitoneal abscess caused by a ruptured appendix. Following the operation she had been critically ill for a number of days, but was discharged as well, March 4, 1916. The hospital records do not have any statement from the attending surgeon as to whether or not the appendix was removed. April 27, 1917, she came for relief of very severe pain in the entire lower abdomen. The temperature was 101, the pulse 120, and there was intense nausea and profuse vomiting. The present severe clinical condition had been present about thirty-six hours; but for several days the patient had not felt entirely up to par. Up to about forty-eight hours before her admittance to the hospital she had felt well excepting that for about two weeks she had had more or less residual tenderness in the lower right abdominal quadrant, cramplike pains that at times were quite severe, and more or less tendency to nausea. The climax seemed to come about thirty-six hours before admittance, when she had a frightful sudden attack of pain in the lower abdomen. The bowels became distended, no relief was obtained from cathartics, which were promptly vomited, and very little from enemas.

Examination.—The girl looked far more ill than the recital of the history would indicate. She was of a dirty greenish yellow color, was covered with a cold, clammy sweat, and moaned with pain. The lower abdominal muscles were extremely rigid, and there was abdominal distention. The muscular rigidity was of a boardlike nature on the right, and one got the indistinct feeling of a mass in the lower right quadrant. In view of the previous operation and the present findings the diagnosis was an intra-abdominal abscess, of appendical origin, with a low grade intestinal obstruction.

Operation.—Entrance to the abdomen was through the old operative incision, taking out the scar. The omentum was adherent to the intestine and pelvic contents. A large abscess was found on the right at the level of the pelvic brim. I went through the adherent omentum into the abscess, because removal of the adhesions seemed unwise in the condition of the patient. The abscess contained something like a quart of intensely fetid pus, the odor of which was frightful, and two live lumbricoid worms. The abscess wall had a look that was very suspicious of tuberculosis. No search was made for the appendix, and only a very limited one to see if there was any opening between the intestine and the abscess cavity. None was found, and the cavity was drained by a large cigaret drain, the abdominal incision being left with a rather generous opening. It was felt that one had better take chances with an incisional hernia than with any failure to drain such a fetid mass.

Postoperative Course.—The condition of the patient for the first seventy-two hours following the operation was critical.

She was given a continuous rectal drip of sugar solution with one intravenous injection of physiologic sodium chlorid solution. Careful examination of the stools for several days disclosed no more worms. The patient was discharged from the hospital May 24 with a solid wound and in good physical condition. She has remained well up to date.

PREPARATION OF MEDIUMS: A NEW HYDROGEN-ION CONCENTRATION METHOD*

LYMAN J. STRONG, M.D. (BUFFALO)
First Lieutenant, M. C., U. S. Army
NEW YORK

That bacteria may grow, the environment must be of about the same acidity or alkalinity; for bacteria to be pathogenic, this environment must be near the alkalinity of the human tissues. The adjustment of mediums to this alkalinity by methods now in common use is time consuming and often unsatisfactory. Carefully made standard solutions, with fine titration, often produce a product after sterilization that is found to have an entirely different reaction. If separate tubes or flasks are investigated, one is surprised to find the wide variation that exists in different containers of apparently the same medium. This is especially true of sugar mediums.

Much work has been done on indicators, but each has its fault as a general indicator: Litmus is not sensitive enough. Andrade's is suited only for aldehyd formers. Fuchsin does not have a suitable end-point. Brilliant green is inhibitory. Phenolphthalein is not indicating in acid. Others are either antiseptic or their end-points are wrong.

About two years ago, while I was working with the hydrogen-ion concentration of human blood serum, it struck me that phenolsulphonephthalein might be used: it has a fairly long end-point, which is of the same alkalinity as the human tissues; it is injected into the blood stream in kidney functional work with no damage to the human tissues. A year ago we began using it at the Buffalo General Hospital, and the results were so good that all other methods have been discarded. Two stock mediums are all that we use now: one fluid broth, the other solid agar. The preparations are the same except that one contains agar.

PREPARATION OF MEDIUM

Broth is prepared from minced lean beef, 2⅕ pounds (1,000 gm.), and distilled water, 1,000 c.c., which are infused in the ice box for twenty-four hours, filtered through glass wool, heated to the boiling for two minutes, and again filtered through glass wool. Now are added peptone, 10 gm.; sodium chlorid, 5 gm.; enough water to make 1,000 c.c., and the white of one egg. The mixture is heated to a boil and filtered through glass wool until clear. A 1 c.c. ampule of phenolsulphonephthalein is added. About 5 c.c. are poured into each of two test tubes. To one test tube a drop of any acid solution is added; to the other, a drop of sodium hydroxid solution. Then, drop by drop, are added acid (hydrochloric acid solution) or alkali (sodium hydroxid solution) until the color of about 5 c.c. poured into a third test tube is between the color of the other two test tubes. The hydrogen-ion concentration of the entire batch of medium will now be about p_H 7.5 This is the same as that of average human blood serum. Should a precipitate form, it may be filtered again through glass wool; paper or cotton may be used for filtration, but these remove the vitamins, and unless serum or blood are to be added later, some bacteria will not grow well.

ADVANTAGES

The advantages of this method are:

1. No standard solution is used: any solution will do.
2. Any tube that changes reaction can be told at a glance and discarded before inoculating.
3. Growth always produces a change in color.
4. Growth of all organisms is much faster and luxuriant.
5. Much time is saved, and there is a more desirable product.

BONE SKID

W. C. F. WITTE, M.D., AND RAYMOND L. SCHULZ, M.D., MILWAUKEE

During the open reduction of two cases of fractures of the lower end of the tibia that were somewhat impacted and had remained unreduced for periods of two weeks, considerable difficulty was encountered. The fractures were both of the spiral type, with an irregularly serrated fracture line and overriding and rotation of fragments. There was so much muscle tension during the period of contraction that the bony fragments could not be separated to any extent. Angulation and bringing the fragments together in proper alinement were impossible on account of the proximity of the fractures to the lower end of the tibia. A curved periosteal elevator was used as a pry, but it slipped up into the medullary cavity of the bone as soon as it got beyond a certain angle. To obviate this, an instrument was made, having a short curved tip and a larger secondary curve in the opposite direction immediately following (Fig. 1). Longitudinal grooves were cut into the concave side of the second curve, to serve as a guide for the roughened edges of the bone to slide in. This instrument was used in another case and found to be a great aid in prying the fragments of a fracture apart so as to make reduction much easier. Further cases for testing the value of this instrument have not been available for some time. It was thought best, therefore, to report the idea with the hope that others might have an opportunity to try it.

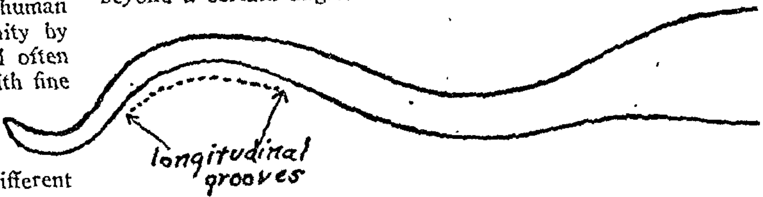

Fig. 1.—Curved portion of bone skid, same size.

The fracture is exposed in the ordinary way, and if the fragments cannot be reduced readily, the tip of the bone skid is inserted beneath the overriding fragment in such a way as to engage the edge of the fragment lying beneath it, as shown in Figure 2. The handle of the skid is then swung around so that the edge of the overriding fragment glides in the grooves of the second curved portion, which then acts as the fulcrum of a lever to pry the fragments apart. At the same time, the fragments are manipulated and guided by bone forceps so as to bring the fragments into proper alinement. When this is done, the skid is removed and the fragments are allowed to approximate, and are fastened together as desired. Since a tremendous leverage can be obtained, care must be used to avoid breaking out a segment of the cortex of the bone.

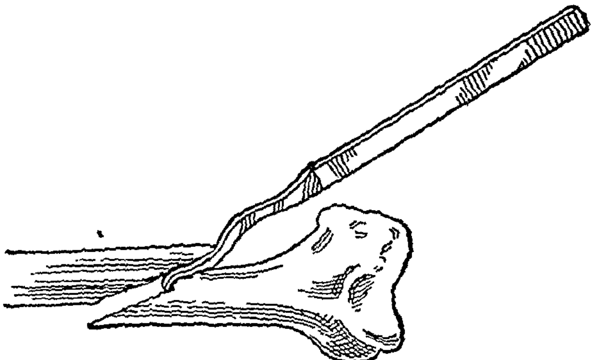

Fig. 2.—Use of bone skid for bringing the ends of a fractured bone into apposition.

Insomnia.—Sleeplessness is due to many causes. The most fertile cause is irritation of the brain by messages from the abdomen. I would venture so far as to say that flatulent dyspepsia is the cause of nine out of ten cases of insomnia.—G. King Martyn, M.D., *Medical Press and Circular.*

SATURDAY, FEBRUARY 8, 1919

ENCEPHALITIS LETHARGICA: A NEW DISEASE?

Last spring considerable alarm was awakened in Great Britain at the outbreak, notably in London and Sheffield, of cases of illness presenting a group of unusual cerebral or cerebrospinal symptoms. The distinctive features appeared to be those of an acute general disease associated with a condition of increasing languor, apathy and drowsiness, passing into lethargy; progressive muscular weakness passing into complete disablement, and a combination of various cranial nerve palsies, of which ptosis, squint and nystagmus were characteristic signs. The cases were provisionally diagnosed botulism, toxic ophthalmoplegia, epidemic stupor, epidemic lethargic encephalitis, acute polioencephalitis, polioencephalomyelitis, bulbar paralysis and Heine-Medin disease. There is some evidence that a comparable illness has appeared in France and in Austria.

At the outset there was a tendency to ascribe the obscure malady to food infected with *Bacillus botulinus*. The difficulties then prevailing in the war-time food situation helped to focus attention on possible outbreaks of botulism. Other hypotheses presently were based more directly on the nervous symptoms such as appear during an acute specific fever which may affect any part of the central nervous system and cause a variety of manifestations dependent on the portion affected. Accordingly, suspicion as to the appearance of acute poliomyelitis was prominently raised. Still other suggestions referring the etiology to some nonbacterial poison, such as benzin used in the manufacture of certain butter substitutes, or to vitamin deficiencies in the dietary, were pressed for recognition.

An investigation of wide scope was undertaken by the experts of the Local Government Board through their Medical Research Committee.[1] The recently published results practically negative the diagnosis of botulism, so far as association of the illness with infection from food is concerned. Dr. McIntosh of the London Hospital failed entirely to recover the bacillus of Van Ermengem from tissues and fluids in fatal cases and from articles of food that had been regarded with suspicion. He was also unable to obtain evidence that the serum from recovered patients agglutinated *Bacillus botulinus* or protected animals from its toxin. In fact, the histologic examination of the changes in the nervous system pointed to an acute infection rather than to an intoxication. Furthermore, the epidemiologic evidence was scarcely in harmony with a food-poisoning theory; thus, for example, two typical patients were breast-fed infants. Finally, botulism appears to be a nonfebrile disease according to the most recent studies of its manifestations.[2]

The British investigators have also made careful inquiry into the possible identification of the new disease with acute poliomyelitis. Professor Marinesco, the neurologist of the faculty of Medicine at Bucharest, assisted in ascertaining the pathologic features related to the nervous systems of the victims. His observations, in addition to those of McIntosh, show sufficient points of divergence from the classic picture of poliomyelitis to furnish presumptive evidence against the view that the English cases were merely encephalitic varieties of poliomyelitis. None of the postmortem material yielded the pleomorphic coccus described by Rosenow in acute poliomyelitis. Cultures from the blood were invariably sterile, and cultures from the cerebrospinal fluid, nasopharynx and feces failed to show the constant presence of any particular class or type of micro-organism. The central nervous system showed an inflammatory process resembling that observed in general paralysis, syphilis, sleeping sickness and acute poliomyelitis, and the diagnosis between the lesions and those of the last named disease is difficult from the histologic indications alone.

The strong clinical, epidemiologic and pathologic evidence that encephalitis lethargica is distinct from classic poliomyelitis is supported in a way by the animal experiments undertaken. Inoculations with emulsions of nervous material, under conditions in which poliomyelitis has been transmitted to monkeys, failed to produce a paralysis. Sir Arthur Newsholme, the medical officer of the Local Government Board, frankly admits that all these negative findings are far from satisfactory. The speedy cessation of the outbreak has put an end to further investigation at present. In suggesting that the disease is a malady *sui generis*, anatomically and clinically distinct from analogous affections, we need not forestall further study whenever a suitable opportunity is presented by the identification of suspicious cases. As the first necessity for such a course is early and complete information of all cases of the disease in different places, it has been decided as a temporary measure to make encephalitis lethargica compulsorily notifiable for a period of one year throughout England and Wales.

[1] The Report of an Enquiry into an Obscure Disease, Encephalitis Lethargica, Reports to the Local Government Board on Public Health and Medical Subjects, New Series No. 121, London, 1918, p. 74.

[2] Dickson, E. D.: Botulism, a Clinical and Experimental Study, Monographs of the Rockefeller Institute for Medical Research, No. 8, July 31, 1918.

From a practical standpoint it has been suggested that the outbreak which has been described may be associated with a breakdown of immunity. Lowered resistance to a usually harmless saprophyte or a "conditional" parasite may be conceived to permit harm from organisms ordinarily harbored with impunity. The practical indication in the absence of further knowledge follows familiar hygienic dicta. We must, says Newsholme, enlist all the resources of personal and public hygiene in an endeavor to influence favorably the potential energies of the body and tissue cell resistance. At the same time, he adds, it is clearly of importance to pursue research not only to ascertain what pathogenic agent is concerned, but also into the factors of individual predisposition and correlated resistance, the variations of which are subject to so many influences.[3]

THE RESULTS OF AERIAL SHOCK AND THE CLASSIFICATION OF THE INJURED

As an outcome of the war, light has been thrown on many obscure neurologic problems. In this domain the effect of shell explosions on the organism has offered a particularly fertile field for observation and research. Now that the war is over, it appears that in no field will the ultimate results on the individual be so difficult to evaluate as in this. And, accurate evaluation is important not only in the interest of the state, but in some cases at least in its bearing on the recovery of the patient. Bonnet[4] has prepared a description and in some measure an explanation of injuries resulting from aerial shock and not directly due to missiles or from poisoning from the gases generated. In his conclusions he briefly directs attention to the classification and pensioning of soldiers injured by shell explosions as recommended to the French authorities by French neurologists.

After considering the results of the experiments of physicists on the effects of explosions, and focusing attention on the extent and power of the aerial disturbance from the various explosives used in warfare, Bonnet passes to observations made at the front by himself and his confrères, under what must have been great difficulties. He agrees with other competent observers that it is the shock of the advancing air wave generated by the explosion that causes the damage, and that the extent and severity of this depends on the locality of the burst—*open* spaces, trench or dugout. None of these points are new, but they cannot be too often repeated, as they are fundamental to the explanation of the results of explosions.

Observations were made on the arterial pressure of soldiers during shell fire. It was found that the bursting of shells invariably increases arterial pressure in those in its vicinity; but if no pathologic lesion results, the pressure returns to normal, after a period, depending on the amount of shell fire and the condition under which the burst occurs. This increase could be demonstrated in old soldiers, even though they showed not the least emotion at the burst of the shell and were protected from danger. Bonnet concludes that the shell burst affects all people in the vicinity, and that these variations in arterial pressure are not emotional but a reflex sensory disturbance from the atmospheric pressure, the earth vibrations and the noise. He admits that in many these reflex sensory disturbances are influenced and increased by psychic and emotional influences, such as insomnia, fatigue and the association of ideas. While the influence on the organism of the increase of pressure from one or two shells may be negligible, this increase coming from thousands of shells has to be reckoned with in those with latent tendencies to certain diseases, such as syphilitics and those with an unstable sympathetic system. It is to this, together with fatigue, that he attributes the increase in warfare of such diseases as general paralysis and exophthalmic goiter.

The explanation of nervous and pulmonary lesions following shell explosions offered by Bonnet is that the aerial wave compression acts primarily on the superficial capillaries and blood vessels as well as those of the abdominal cavity: in short, on those not protected by nature from pressure. There is thus formed a blood column, which is driven like a battering ram into incompressible cavities like the thorax and the cerebrospinal cavity. As a result, the smaller vessels in these cavities, many of them terminal, may rupture or thrombose, causing partial anemia of surrounding tissues with a varying amount of injury. The eye and the ear are especially liable to suffer, the former by its position exposed to pressure and the latter by its physiologic adaptability to receiving pressure. It is undoubtedly true that the internal ear may be damaged without rupture of the drum, if this structure is sufficiently elastic. Gas emboli play little part, because the compression wave is of too short duration.

The question is often asked: Why do concussion effects occur so little among artillerymen? Bonnet would answer this by saying that in gun fire the explosion is dynamically feebler and is purposely directed to be of relatively long duration in order to give movement to an object, while the explosion of the shell results in the sudden development of enormous energy transmitted onward as atmospheric waves.

The early separation of shock patients from hysterical patients is advisable. As early as possible, patients with organic or mental shock should be sent for treatment to the rear, the hysterical patients returned to the front. Those with doubtful or troublesome cases, he believes should be sent to a special neurologic center, for the sooner psychotherapy is practiced by a specialist the better for the patient. He assigns an important rôle to the sympathetic system in shock, and advises not only that the patient be kept quiet but also that suprarenal and thyroid treatment be used judiciously.

---

[3] The term "encephalitis lethargica" seems to have been applied first by von Economo, who described the symptoms as they occurred in Austria (Wien. klin. Wchnschr. 30:581, 1917.

[4] Bonnet, Maurice: Contribution à l'étude des effets des explosions de guerre sur l'organisme, Nancy, A. Crépin-Leblond, 1918.

Quite important is the suggestion in regard to compensation for injury or disease caused by warfare. The French soldier incapacitated for service is usually classed as réformé No. 1 or réformé No. 2. In the réformé No. 1 class are soldiers who are discharged permanently as being incapacitated for further military service. In the réformé No. 2 class are soldiers who are discharged temporarily because of some incapacity which, however, is remediable. In war time these soldiers are reexamined every three months, and then may be returned to service or again temporarily discharged for three months. The man in the réformé No. 1 class may receive a pension if his condition in life shows that he requires it, but he always receives a lump sum as an indemnity based on the amount of disablement and calculated in percentages of total disablement from 10 to 100 per cent. On the recommendation of Babinsky, the Society of Neurology and Psychiatry adopted the following conclusions:

1. Hysterical patients should be granted neither discharge nor indemnities. If the hysteria is associated with organic disorders, no cognizance of the hysterical manifestations should be taken in valuing the degree of incapacity.
2. In cases of reflex nervous manifestations following war traumatism that prove refractory to treatment, the patient should be transferred to an auxiliary service or be discharged temporarily with an indemnity valued at from 20 to 50 per cent. of total disablement.
3. For marked neurasthenic states without organic disorders or mental trouble, no indemnities should be granted and only exceptionally discharge, more often auxiliary service.

In regard to mental conditions, the same society adopted the following recommendations:

> In acute states, even emotional (*même purement émotionelles*) following shock, the soldier should be discharged with a rate of incapacity between 10 and 100 per cent. without regard to predisposition. For dementia or definite psychic enfeeblement following traumatism, the soldier should be discharged as réformé No. 1 with a rate of incapacity of from 50 to 100 per cent. For chronic psychosis following shock, the soldier should be classed as réformé No. 1 with an incapacity rate of from 20 to 80 per cent. In mania or melancholia first appearing after traumatism, there should be given a temporary discharge with an incapacity rate of from 10 to 40 per cent.

At a meeting of the chiefs of centers of the French medical service with the undersecretary of state for health, it was decided that general paralytics should be discharged in Class 2 (réformé No. 2) except in particular cases in which it was proved that it had been aggravated by military service. In these a rate of from 60 to 80 per cent. of incapacity should be given. Epileptics should be placed in Class 2 except when traumatism or infection antedated the appearance of the first grave epileptic seizure. These should be grouped in Class 1 (réformé No. 1) with an incapacity rate of from 10 to 80 per cent.

To these groups Bonnet would add cases of exophthalmic goiter. He rightly insists that pulmonary lesions and lesions of the organs of sense due to shell explosion ought to be classified and rated as war wounds. He recommends that from time to time those discharged should be reexamined because a number invalided are capable of improvement.

Such detailed study as is being given in all the Allied nations to the problems of the wounded and otherwise incapacitated soldier must inevitably yield much that is of value to the future of medical science. It is, moreover, an adequate guarantee that the victorious nations realize the extent of their obligation to the fighting man and will do their utmost to meet that obligation.

LITERATURE AS AN AID TO RESTORATION

The war, which has in greater or lesser degree affected all the civilized nations of the earth, has given rise to novelties of performance and innovations of thought entirely unanticipated. Aside from the institution of new devices and operations that have demanded unusual ingenuity on the part of both the offensive and the defensive elements concerned, the very magnitude of many of the projects has tended to make ancient provisions in relation to them inadequate if not actually useless. The proportions of the war have been so vast, the numbers involved so huge, that new types of ability have been called for to manage the enormous machinery and its indescribable complexity. Tremendous efforts have become necessary to alter the inertia of traditional procedures.

A striking illustration of this, as it pertains to men rather than materials, is afforded by the problem of the care, reeducation and return to civil life of disabled soldiers and sailors. Medical attention has, it is true, been bestowed liberally on the unfortunate victims of previous wars. Today, however, there is a well founded realization that something more than first-class hospital treatment and loudly voiced gratitude is due to those who have become disabled in their response to the call of duty. The thought of the disabled, wrote Lord Charnwood, cannot fail to awaken first of all a deep feeling of compassion, and, in a sense, of course, it claims all our compassion. But something is wrong, he adds, with the man in whom that sentiment can remain merely or even mainly sorrowful. All visitors to military hospitals have the same experience. They go there expecting to see something profoundly sad; they do, in fact, see sights more horrible than they had previously imagined; but, Lord Charnwood concludes, the devotion and resourcefulness of the healer, the courage and the constant unselfishness of the sufferer, surpass their expectation no less; and they come out full of a strange, deep exhilaration, an enduring remembrance in which the solemnity of death is quite swallowed up by the joy of life.

As never before, it has become necessary in every country involved in actual fighting, to carry the indispensable encouragement beyond the period of hospital residence and to institute on an elaborate scale schemes of practical helpfulness. Men must be encouraged materially and, above all, spiritually, to "carry on." Pity of the stagnant sort must be replaced by positive organization "for training the disabled man, for opening to him a satisfactory place in life, and incidentally for carrying his cure farther."

We have already called attention to some of the agencies that have been created in this country to do what no pension system can accomplish.[1] A product—perhaps it should be designated a tool—of the restorative scheme is seen in a diversity of literary efforts intended to further the plan. As early as July, 1917, a journal entitled *Recalled to Life* was established by Lord Charnwood. Under the new name of *Reveille*, the quarterly has become a review of all that is being done abroad for the disabled sailor and soldier. Under the editorship of John Galsworthy, two numbers published since last August have exhibited a truly unique contribution to the story of what restoration means "to those who are being restored, to those restoring them, but even more—to the nation at large." Renowned names in literature and art have created a unique magazine which aims to steer its readers between the roads of "facile optimism" and "easy-going pessimism." *Reveille* breathes forth a new spirit of encouragement, and illustrates in a splendid way how psychologic and material forces can make life useful even under depressing conditions. The medical fraternity will do well to study these novel literary devices as hitherto unappreciated aids in the art of restoration.

INTESTINAL PROTOZOA IN THE TROPICS

Of the numerous and varied forms of life that are known to enter and at times inhabit the alimentary tract of man, comparatively few, aside from bacteria, have established a reputation for pathogenicity. Larger organisms like the intestinal worms have, of course, long been regarded as highly detrimental. Their noxiousness has been ascribed primarily to the harm these parasites might do mechanically or locally; and not until more recently has the possibility of the production of soluble poisons by the invading organism been reckoned with. The occurrence of eosinophilia in the leukocytes of the blood is itself a significant indication of response to chemical products rather than to the mere mechanical irritation of the parasite.

Among the smaller forms, the trypanosomes and coccidia are justly the objects of grave suspicion whenever they exhibit their presence in the body. Some of the intestinal amebas, like the *Ameba coli*, have also given indications that they may produce toxic products. Various intestinal flagellated and ciliated protozoa, however, appear to exist in the intestinal tract for long periods without causing any trouble to the host. They seem not to become obligatory parasites in the objectionable way of other forms mentioned. Consequently they have received little consideration from a pathogenic standpoint.

The medical zoologist[1] of the University of the Philippines recently stated that the time has arrived when workers in the field of parasitology should fairly face the situation presented by the intestinal flagellates. They have been under suspicion for many years, during which time there has been gradually accumulating a mass of evidence against them. No progress will be made if we are to continue to employ, as our criteria of pathogenicity or nonpathogenicity, the presence or absence of blood and pus in the stools.

It is conceivable that lack of resistance or some other change on the part of a host may confer new powers on a presumably harmless parasite. There can be little doubt that altered environments profoundly influence the pathogenicity of bacteria. Why should a similar possibility not arise in the case of other microbiotic forms? Pending the extension of knowledge about them we may be prepared to expect actual invasion and destruction of tissues even by supposedly nonpathogenic forms. Haughwout adds to this possibility the warning that such organisms may actually interfere with absorption because of the adherence of large numbers of parasites to the surface of the epithelium. Serious mechanical irritation of mucous surfaces even by these lowly invaders is likewise not excluded. The production of substances of a high or low degree of toxicity, even if they are merely the products of parasite metabolism, needs to be reckoned with more than it has been in the past. The experience of trained parasitologists in the tropics where alimentary protozoan invasions of the body are more common seems to point to the importance of more intensive study of the possibilities in this field. Such apparently unexplainable conditions as "philippinitis"—the "tired feeling" ascribed without strict justification to heat, sunlight or other climatic factors—may find a solution in the frequent presence of supposedly harmless protozoa. At any rate, in the absence of more detailed knowledge at present there is some propriety in the warning of Haughwout that "the flagellated intestinal protozoa should be viewed with suspicion and regarded as pathogenic until the contrary is proved beyond dispute."

Current Comment

THE BLOOD PLATELETS

The "third class of formed elements" of the blood, now generally spoken of as blood platelets, has been the subject of much speculation and almost irreconcilable clashes of opinion. The French hematologist Hayem at one time regarded these structures as stages in the formation of red blood corpuscles. There can be no doubt, to quote the language of one physiologist, that the stuff known as blood platelets stands in some very important relation to the clotting of the blood. The greatest uncertainty relating to this may be expressed by the question as to whether they are morphologic structures essential in initiating the process of coagulation or whether, on the contrary, they are a product of this change. Indeed, they have been described as liquid crystals rather than structural cells. The microscopists know that the platelets have a specific affinity for basic dyes and that even after their first appearance they are very unstable, tending to undergo further alteration unless they are permanently fixed by some suitable procedure. It has even been said that the various fixing fluids that have been recommended for demonstrating the blood platelets actually produce rather than merely preserve them. Such is the uncertainty. If a determination of the origin and significance of the platelets is to be appealed to in unraveling the complexity of the problem of blood clotting, it is certainly not without significance that these illusory structures are not found in other than mammalian bloods, despite the fact that the circulating fluid of fishes, birds and reptiles clots. Nor have the platelets been discovered in the serous fluids of mammals. Attention is naturally called in this connection to the coagulable lymph. The reports of several investigators on the occurrence of platelets in lymph reveals a disagreement among the histologists of this fluid.[1] The latest opinion based on experimental evidence, from Jordan[2] of the University of Virginia Department of Anatomy, completely substantiates Howell's assertion that the lymph from the thoracic duct lacks platelets completely. If, then, it is asked how lymph can contain clot-facilitating substances generally believed to be liberated by platelets, the explanation may be found, according to Jordan, in the instability of these elements. In their passage (relatively slow as compared with the blood circulation) through the lymphatics to the thoracic duct, he suggests, the relatively small number that may have entered the system may have entirely disintegrated, meanwhile contributing the relatively small amount of prothrombin and thromboplastin characteristic of lymph; to which the lymphocytes under favorable conditions may contribute a certain additional amount, as suggested by Howell. Considering the origin of the bulk of the lymph from the plasma by way of the tissue spaces, and the continual disintegration of blood platelets, Jordan adds, the presence of these elements (thrombin and thromboplastin) in lymph can be accounted for, at least in part, on the basis of this relationship between blood plasma and lymph.

THE GALLBLADDER AND THE SECRETORY PRESSURE OF THE LIVER

So far as the bile may be an excretory product, furnishing a device for ridding the organism of disintegration fragments of the blood pigments, its discharge should be more or less continuous; as a fluid facilitating digestive or absorption phenomena, its presence is needed only at certain active stages in the alimentary cycles. The exigencies of the body, says a recent writer,[1] therefore require a continuous excretion of bile by the liver, but a discontinuous entry of this fluid into the small intestine. The discontinuity of the entry of a continuous secretion into the intestine is secured, in the majority of animals, by the existence of a gallbladder, a diverticulum from the bile ducts, in which bile secreted during the intervals between periods of digestive activity is stored up. Not all species, however, have a gallbladder. Its place is taken to some extent by rather large ducts, as in the case of the horse. Judd and Mann[2] have ascertained that all of the extrahepatic ducts dilate after the removal of the gallbladder. This result seems to be due to interaction of the pressure exerted by the liver and sphincter at the duodenal end of the common bile duct. A logical inquiry, therefore, concerns the question of the natural secretory pressure in such species as have no gallbladder. Is it altered in any way that might suggest some compensatory activity to replace the functions of the missing bladder? The pressure at which the bile is secreted has a variety of bearings on the phenomena that may be staged with reference to this secretion and the channels in which it is confined. According to the latest researches of Mann and Foster[3] at the Mayo Clinic, the presence or absence of a gallbladder bears no relation whatever to the secretory pressure of the liver, although the pressure varies considerably in the various species of animals both with and without gallbladders.

THE RETURNED TUBERCULOUS SOLDIER

The returning tuberculous soldier is not likely to prove a serious problem in this country, although it is one to which a certain amount of consideration must be given. There is no difficulty with the bed patient; at least he does not spread infection. The problem is the man who is suffering from the disease in the incipient form. He can usually be cured or the disease checked, but the treatment is slow and tedious. Sanatorium treatment has many advantages, but sanatorium life becomes irksome and monotonous. Much thought has been given to this subject in Europe. It may be instructive, therefore, to learn of some projects devised to relieve this situation on the other side of the Atlantic. Dr. P. C. Varrier Jones[1] believes that occupation is indicated for all consumptives who are able to work, such work, of course, being regulated in proportion to the condition of their health. He directs attention to the fact that the problem is not purely medical, but that psychology, sociology and medicine are mingled as in no other medical problem. The human element must be the touchstone. The gist of his argument is that, as no man can be expected to submit to the monotony of institutional life for an indefinite period, the remedy is to graft the colony principle on existing sanatoriums. Patients may be employed at their own or allied trades or at suitable occupations that have been taught them. In effect, the suggestion is made that village communities for the especial use of tuberculous soldiers should be established, and that these should be well provided with the amenities of life. One such community has been in existence in England for some time and has thoroughly justified its establishment. It is kinder to the returned tuberculous soldier and better for the community that whenever possible he should be given every facility to earn his living and taught a trade if necessary. The village community system appears to present several advantages for this purpose.

SULPHATES AND NUTRITION

Most foods consumed by man contain mineral or inorganic constituents. Indeed, they are present in all food in the natural state, but sometimes are removed during the processes of refinement such as sugar and the oils undergo. It is taught that inorganic compounds are indispensable in the diet. No less than nine elements—calcium, sodium, potassium, iron, magnesium, sulphur, iodin, phosphorus and chlorin—are included under this caption; yet ordinarily little distinction is made between them with respect to their usefulness to the organism. The commonly used foods vary widely in their content of these elements; thus the cereals furnish little calcium, whereas milk is rich in it. The distribution of chlorin and sodium is likewise decidedly varied. Osborne and Mendel,[2] in a study of the inorganic elements in nutrition, have called attention to the uncertainty of our knowledge as to the indispensability or the minimal requirement of any of the inorganic constituents of the dietary, with the possible exception of calcium and phosphorus. They have pointed out the apparently extraordinary capacity of the body to adjust itself to a varying supply of common salt, and they suggest that what is true of sodium chlorid may apply to other elements in equal degree. Certain it is, at least, that the inorganic elements as they happen to occur in the natural foods do not necessarily represent the optimal or even the minimal needs of the individual. A new illustration has been furnished by Daniels and Rich[3] of the Department of Home Economics at the University of Wisconsin. They have found that despite the occurrence of inorganic forms of sulphur in natural foods so that probably no normal diet is ever free from them, the sulphates are not used to build the organic sulphur complexes of the body. Animals cannot use inorganic sulphates to replace the sulphur-containing amino-acid cystin derived from the proteins. It therefore follows as a corollary that the proteins furnish more than nitrogenous groups to the organism. They must be depended on for the indispensable sulphur-yielding groups also.

Medical Mobilization and the War

Personnel of the Medical Corps

For the week ending January 31, the Medical Corps contained 23,424 officers, a decrease from the previous week of 924. The Medical Reserve Corps contained 626 officers. The total number of medical officers discharged since the beginning of the war is 9,966.

Convalescent Center to Be Established

A convalescent center is to be established in Chickamauga Park under the immediate command of Brig.-Gen. William S. Scott. It is believed that the hospital will be large, consolidated with several of the hospitals that are now being maintained. The decision to establish this center was made known, January 20, after a tour of inspection by Major McLain of the Surgeon-General's Office in charge of the convalescent hospitals in the southeastern department.

New Hospital Construction

Additional hospital construction will be undertaken by the Construction Division of the Army as follows:

Walter Reed General Hospital, Washington, D. C., alterations and additions to the receiving wards and construction of a building for automobile repairs and for mechanics necessary for physical reconstruction exercises.

At Debarkation Hospital, No. 51, Hampton Roads, Va., nurses' quarters, barracks for enlisted men as well as mess barracks for them, diet kitchen, alterations to existing barracks and sheds, a new wharf and a hospital train track and shed. The estimated cost at this point is $195,000.

Eight new ward buildings at Letterman General Hospital, San Francisco, which will increase the capacity of that institution from 1,400 to 1,800, at a cost of about $75,000. The addition to the power plant will cost about $6,000. Two structures for the educational department to be used in training wounded soldiers, and a kitchen capable of preparing meals for 2,400 patients.

Administrative and Construction Work in Hospitals

The War Department authorizes the following statement from the Office of the Surgeon-General:

Officers and enlisted men are needed by the division of physical reconstruction for administrative and instruction work in hospitals. Men who have had technical trade, commercial or agricultural training and experience are especially desired as instructors in the curative workshops.

Authority has been granted by the War Department to transfer to the reconstruction division any commissioned officer, noncommissioned officer, or enlisted man from any branch of the service who is no longer needed in his present assignment and who desires the transfer.

These men will be sent to hospitals functioning in physical reconstruction. The program is now in operation in 25 hospitals with an enrolment of 10,000 disabled soldiers in bedside and ward handicrafts and studies, technical and trade work in shops, agricultural work in hospital farms and gardens, stenography, stenotype, typewriting and other commercial work, and in general academic work. More than 100 commissioned officers are in charge of the administrative service and in supervisory positions, and nearly 500 enlisted men are in service as instructors.

[3] Daniels, Amy L., and Rich, Jean K.: The Rôle of Inorganic Sulphates in Nutrition, J. Biol. Chem. **36**: 27, 1918.

The reconstruction work will last until the hospitals are cleared, probably by the summer of 1919.

Formation of Commission Sanitaire Des Pays Alliés

A health commission of the Allies has been formed containing representatives of most of the large nations allied against Germany. A subcommission was recently appointed by Professor Santoliquido, delegate from Italy, and president of the commission. The subcommission will meet in Paris on the first or fifteenth of each month to consider the most important sanitary problems regarding demobilization, the occupation of territory formerly invaded, the military occupation of enemy territory as related not only to the health of the troops, but also to the civilians concerned. The personnel of the subcommission is: president, M. le Professeur Santoliquido, Conseiller d'Etat, Délégué de l'Italie dans le Comité de l'Office International d'Hygiène publique; M. le Médecin Principal de premiere Class Maistriau, Commandant du Groupement Régional du Service de Santé à Rouen; M. le Médecin Général Jan; M. le Col. Richard P. Strong, Director Department of Medical Research and Intelligence, A. R. C., M. le Col. W. W. O. Beveridge, C.B., D.S.O., Assistant Director of Medical Services for Sanitation, Professor of Hygiene Royal Army Medical College; M. le Médecin Major Levi; M. Coussol; M. de Lieut.-Col. Médecin Professeur A. Castellani; M. de Cazotte, Ministre Plénipotentaire, Directeur de l'Office International d'Hygiène publique; M. le Docteur Pottevin, Directeur Adjoint.

Orthopedic Clinic Fort Snelling

At the request of the Minnesota Academy of Medicine a clinical evening was arranged for the medical profession of Ramsey and Hennepin counties by the orthopedic staff of U. S. General Hospital No. 29, Fort Snelling, Minnesota. This clinic was held Thursday evening, Jan. 23, 1919, at the Post gymnasium. About 400 of the profession of the twin cities attended. Col. W. J. Mayo and Colonel Sullivan of the Surgeon-General's office were also present. A carefully worked out program was presented with the intention of giving a general outline of the various phases of the orthopedic service at the hospital. Cases were shown accompanied with brief histories and exhibited the various war wounds and the degrees of function accomplished by means of surgical and physiotherapeutical measures adopted. The wealth of interesting cases collected from about 2,000 overseas men furnished a limitless variety for exhibition and inspection. The program included: 1. Presentation of Unusual Overseas Casualties. 2. Presentation of Overseas Orthopedic Joint Results. 3. Presentation of Local Physiotherapy Results. 4. Exhibition of Splints, Provisional Limbs and Limbless Patients. 5. Presentation of Occupational and Shop Activities. 6. Lantern Demonstration of War Wounds and Results of Orthopedic Surgical Treatment. The orthopedic staff is made up of the following officers: Major E. A. Rich, chief of service; Capt. E. A. Klein, asst. chief, in charge of workshops, artificial limbs; Capt. C. F. Clayton, asst. chief, in charge of all orthopedic physiotherapy; Lieut. E. S. Porter, asst. chief, responsible for service paper work and therapeutics of recreation.

Distinguished Service Medal Awards

The Distinguished Service Medal has been awarded to the following officers:

Major-General MERRITTE W. IRELAND, Surgeon-General, U. S. Army, for extraordinary meritorious and distinguished services. "As chief surgeon of the American Expeditionary Forces he supervised and perfected the organization of the Medical Department in France, and to his excellent judgment, untiring efforts, and professional achievements are largely due the splendid efficiency with which the sick and wounded of the American Army have been cared for."

Major-General WILLIAM C. GORGAS, M. C., U. S. Army, retired, for especially meritorious and conspicuous service as Surgeon-General of the Army in organizing and administering the Medical Department during the war.

Brigadier-General Walter D. McCAW, M. C., U. S. Army, whose "counsel and advices in the earlier stages of the operations of the American Expeditionary Forces were a particular benefit to the effective work of the medical department. As chief surgeon of the American Expeditionary Forces in the later operations in the field he maintained a splendid efficiency of that department at a critical time, solving each new problem presented with wisdom and marked ability."

Brigadier-General ALFRED E. BRADLEY, who "As chief surgeon of the American Expeditionary Forces gave his utmost energy and undivided devotion to the duty of organizing the work of the medical department in France, during a period fraught with untold difficulties. To his foresight was largely due the successful operation of that department when it was called upon to meet the demands that were subsequently made upon it."

Major HORATIO N. JACKSON, M. C., U. S. Army, Burlington, Vt., on duty with the 313th infantry, for acts of Distinguished Heroism, near Montfaucon, France, on Sept. 26 to 29, 1918. "Constantly working in the face of heavy machine-gun and shell fire, he was most devoted in his attention to the wounded, always present in the line of advance, directing the administering of first aid, and guiding the work of litter bearers. He remained on duty until severely wounded by high-explosive shells, when he was obliged to evacuate."

Captain JAMES M. McKIBBIN, M. C., U. S. Army, Hagerstown, Md., deceased. On duty with 306th machine gun battalion, for distinguished heroism near Chevieres, France, Oct. 4, 1918. "During a very heavy artillery barrage, which lasted approximately two hours, he displayed a great coolness and courage in dressing and administering first aid to the wounded. Informed that a sergeant had been wounded and was lying between our lines and the enemy's line, he went to administer first aid to him. While in the performance of these duties, under intense fire, Captain McKibbin was wounded by machine-gun fire and later died from the effects of the wound."

Captain MAURICE C. PINCOFFS, M. C., U. S. Army, Baltimore, on duty with Ambulance Company 1, Second Division, for acts of distinguished heroism near Blanc Mont, France, Oct. 9, 1918. "After a withdrawal of the line had been made, he voluntarily crossed an open field under heavy fire to a small wood, where he located a number of wounded men, whose injuries he dressed and directed their evacuation without further casualties."

HONORABLE DISCHARGES, MEDICAL CORPS, U. S. ARMY

Note.—In the following list, L., signifies lieutenant; C., captain; M., major; L. C., lieutenant-colonel, and Col., colonel.

UNITED STATES PUBLIC HEALTH SERVICE

Surg. J. W. KERR, upon request of Governor of New Mexico,: proceed to Santa Fe for conference relative to address on public health.

Passed Asst. Surg. J. R. RIDLON, relieved at Anniston, Ala., proceed to Fort Stanton, N. M., for duty.

Passed Asst. Surg. W. C. WITTE, proceed to Lincoln, Neb., on special temporary duty.

Asst. Surg. P. M. STEWART, proceed to Ronda, Wilkes County, N. C., to investigate alleged outbreak of influenza. Relieved at Charlotte, N. C., proceed to marine hospital, Stapleton, N. Y.

Asst. Surg. R. R. SPENCER, relieved at Great Lakes Training Station, proceed to marine hosiptal, St. Louis, Mo., for temporary duty.

Asst. Surg. C. R. ESKEY, relieved at Montgomery, Ala., and from temporary duty at the Savannah Quarantine Station. Proceed to the Reedy Island Quarantine Station for duty.

Asst. Surg. THOMAS PARRAN, Jr., proceed to Cullman, Ala., for duty in outbreak of smallpox.

Acting Asst. Surg. G. D. HEATH, Jr., report at Hygienic Laboratory for temporary duty in connection with studies relating to the prophylactic value of antipneumococcus lipovaccines.

Acting Asst. Surg. SAMUEL LICHTENSTEIN, relieved at Raleigh, N. C., proceed to Columbia, S. C., for duty in extracantonment sanitation.

Acting Asst. Surg. S. M. WEYER, proceed to East Las Vegas, N. M., for duty in connection with influenza control.

San. Engineer C. K. HARRUB, proceed to Alexandria, Va., for temporary duty in assisting in the preparation of plans for the construction of sewers.

San. Engr. H. H. WAGENHALS, proceed to Atlanta, Ga., for conference with local authorities in reference to venereal disease control.

Scientific Asst. GEORGE E. McILROY, proceed to New Haven, Conn., for intensive studies in industrial sanitation preparatory to proceeding to Philadelphia, Pa., for duty.

Scientific Asst. MYRON A. BANTRELL, proceed to Philadelphia, Pa., for duty in industrial sanitation.

Scientific Asst. W. H. PRICE, relieved from duty in the District of Columbia, proceed to Anniston, Ala., for conference concerning the milk situation.

Scientific Asst. HENRY W. G. SHYTLES, proceed to Orange, Texas, for duty in connection with shipyard community sanitation.

Medical News

(Physicians will confer a favor by sending for this department items of news of more or less general interest; such as relate to society activities, new hospitals, education, public health, etc.)

ARKANSAS

Personal.—Dr. Charles F. Carnes, Kosciusko, Miss., is reported to be seriously ill in Memphis as the result of an attack of cerebral hemorrhage.

New Officers.—At the annual meeting of the Union County Medical Society at Eldorado, Dr. William N. Elkins, Junction City, was elected president; Dr. W. H. Myers, vice president, and Dr. H. H. Niehuss, Eldorado, secretary-treasurer. ——At the annual meeting of the Jefferson County Medical Society, held in Pine Bluff, Dr. James M. Lemons was elected president; Dr. William Breathwit, vice president, and Dr. John T. Palmer, secretary-treasurer, all of Pine Bluff.——Pulaski County Medical Society held its annual meeting in Little Rock and elected Dr. Caleb E. Witt, president; Dr. Elmer M. Hudson, vice president; Dr. John B. Dooley, secretary, and Dr. William R. Bathurst, treasurer, all of Little Rock.

ILLINOIS

Personal.—Dr. John D. Colt, Litchfield, dean of physicians of Montgomery County, celebated his eightieth birthday anniversary, January 12.——Dr. Bretislav L. Vilna, Cicero, was attacked, January 24, by three men, who robbed him of his automobile.

Addition to Epileptic Colony.—It is announced that the state epileptic colony, Dixon, is to be enlarged with new buildings mostly of the cottage type, and that 700 patients from Lincoln and other state institutions are to be transferred to the colony.

Revision of Nursing Course.—More than 100 members of the First District Nursing Association met, January 21, at the call of the president, Edna L. Foley, to discuss the proposed legislation providing for the revision of the nursing course, and adoption of the registry system. The body recommended the following improvements in the present situation: The establishment of two courses of registered nurses in the state, the first the graduate nurse with three years' training, and the second the junior registered nurse with one year's training; compulsory licensing of every person engaged in the care of the sick; a three years' training course for graduate nurses, a one year's course for junior registered nurses, and the introduction into high schools of a one year compulsory course in home nursing service for all girl students.

Chicago

Base Hospital Soon to Return.—It is announced that orders to return home have been received by Base Hospital No. 11, and the organization will probably be home this month. The hospital has been located at Nantes and has been under the surgical direction of Nelson M. Percy, Lieutenant-Colonel, M. C., U. S. Army, and under the medical direction of George F. Dick, Major, M. C., U. S. Army.

Personal.—Harry D. Orr, Lieutenant-Colonel, M. C., U. S. Army, formerly surgeon of the First Cavalry, Ill. N. G., has recently been made division surgeon of the Thirty-Third Division, which is now on duty on the Rhine premises.——Robert B. Preble, Lieutenant-Colonel, M. C., U. S. Army, returned home, February 2, after seven months' service in France.——Allen B. Kanavel, Lieutenant-Colonel, M. C., U. S. Army, reached Boston on his return home from France, January 22.——Dr. William Blanchard has been exonerated in the case of the death of Clara Schultz, who was killed by the physician's automobile, January 23.——Dr. William A. Evans has been appointed medical adviser of the special commission appointed, January 24, to recommend improvements in the standards and feeding of children in Chicago public schools.

Red Cross Thanks Physicians.—At the meeting of the Chicago Medical Society, January 29, the work of the Chicago chapter of the American Red Cross was described by Mr. Marquis Eaton, its chairman. He states that physicians had donated services estimating to $200,000 to members of soldiers' families requiring medical aid. The Chicago chapter has accomplished the establishment of four base hospitals, the equipment of sixty-nine ambulances, the recruiting of two ambulance companies, the shipment of more than $4,000,000 worth of medical supplies overseas, and the furnishing of medical aid to 18,000 soldiers and their families. More than 12,000 persons have been instructed by the Red Cross in first aid, and more than 500,000 soldiers have been given the benefit of the canteen service. During the recent influenza epidemic, 1,000 nurses were provided by the Red Cross for influenza victims in emergency cases. He announces that the Red Cross intends to keep an emergency storage and equipment for 1,000 cases to be used in the event of epidemics or other emergencies.

IOWA

New Health Bill Drafted.—Dr. Guilford H. Sumner, Des Moines, secretary of the state board of health, conferred with a committee of legislature, January 21, relative to placing a bill before that body relative to venereal disease. The bill provides, first, authority for local boards to make investigation in regard to the prevalence of social diseases, and second, authority to make inspection, examination, and quarantine of those afflicted with such disease.

To Require Admission of Influenza Cases.—At Waterloo the city board of health by mandamus sought to require St. Francis Hospital to admit cases of influenza, which had been refused by the hospital authorities during the epidemic of influenza. The hospital authorities obtained an injunction restraining the board from taking patients to the hospital. The matter is now under settlement in the courts, a hearing in the matter on the mandamus and the injunction having been held, January 8, before Judge C. W. Mullan. At the hearing local physicians and experts from Chicago were heard in connection with the transmissibility of the disease. The Sisters who run the hospital claim that it is not adapted to take contagious cases and they could be admitted only at the serious risk of the other patients.

Personal.—Dr. James M. Barstow, Council Bluffs, who has served for twenty years as medical member of the Insanity Commission of Council Bluffs Division of the District Court, has been reappointed for a two-year term.——Dr. Charles S. Grant, Iowa City, has been appointed a member of the state board of health, to succeed Dr. Edwin E. Harris, Grinnell, who has moved to Boulder, Colo.——Dr. Dennis F. Fitzpatrick, Iowa City, has been appointed physician of Johnson County, to succeed Dr. John G. Mueller, deceased.——The home of Dr. John M. Sturdivant, Cincinnati, was destroyed by fire, January 4.——Dr. Alexander Crawford, Mount Vernon, announces his retirement from practice at the beginning of the year.——Dr. Frank C. Titzell, Iowa City, has been appointed a member of the Harvey (N. D.) Hospital.

LOUISIANA

Superintendent Changes Station.—Dr. Robert S. Curry, New Orleans, who resigned as superintendent of the Mississippi State Institution of the Blind to engage in special work for the state board of health, has been elected superintendent of the Baptist Hospital, New Orleans.

Society Election.—At the annual meeting of the Medical Society of Orleans Parish, the following officers were elected: president, Dr. Hector E. Bernadas; vice presidents, Drs. Wallace J. Durel and Allen C. Eustis; secretary, Dr. Lucian H. Landry, and treasurer, Dr. Foster M. Johns, all of New Orleans.

MARYLAND

Personal.—Seized by two negroes as he was crossing an alley on Chase Street, late Saturday night, Dr. John G. Alexander, Baltimore, was rendered helpless by a blow on the head and robbed of his watch and chain.——Hugh H. Young, Colonel, M. C., U. S. Army, Baltimore, who sailed for France with General Pershing and has been on duty there ever since, returned to his home in Baltimore, January 26, on a short leave of absence. His headquarters are now New York City until he is discharged.——Archibald C. Harrison, Lieutenant-Colonel, M. C., U. S. Army, Baltimore, executive head and chief surgeon of the Maryland University Base Hospital Unit No. 42, is expected to return to the United States early in February.——Dr. Harry Friedenwald, Baltimore, has been appointed medical adviser to the American Zionists' medical unit, which is now in Palestine, and has sailed from New York to join the unit.

Drug Addicts on Increase.—That morphin and other drugs are obtained in Baltimore most flagrantly, that the number of users has increased alarmingly, and that a number of physicians are engaged in a lucrative practice of furnishing narcotics through prescriptions are the statements made recently by Marshal Carter. The Harrison Antinarcotic Act has not diminished the sale of drugs, but opened a channel through which addicts to drugs can obtain ready supplies of narcotics. That there are three times as many drug addicts in this city now as there were a year ago is borne out by the records of the United States internal revenue inspector's office. The inspector testified at the central police station a few days ago that the records of his office showed 750 names in 1917, and that for the year just closed the number has increased to 2,100. A quiet investigation was conducted by the police recently, and the names of physicians prescribing and the druggists furnishing drugs were obtained. Through the system of prescribing for the "reduced treatment," a number of addicts have obtained major quantities and have been able to peddle the drug.

NEW JERSEY

New Officers.—At the annual meeting of the Atlantic County Medical Society, held in Atlantic City, January 10, Dr. Henry T. Harvey, Atlantic City, was elected president; Dr. Henry C. Munro, Jr., Pleasantville, vice president, and Dr. Edward Z. Holt, Atlantic City, secretary-treasurer. The society adopted resolutions deploring the action of the Atlantic County Deputy Board of Free Holders in refusing to furnish funds for the continuance of the work of the mosquito extermination.

Personal.—Dr. Byron M. Harmon, resident physician to Mercer Hospital, Trenton, is one of the fifteen physicians who comprise the relief unit being sent by the American Red Cross for work among Syrians and Armenians.——E. Blair Sutphen, Lieutenant, M. C., U. S. Army, Morristown, who has been ill with typhoid fever at Camp Zachary Taylor, Ky., is reported to be convalescent.——At the annual meeting of the board of health of Gloucester Dr. John A. Beek, Gloucester City, was elected medical inspector. The annual report of the treasurer of the board showed that more than $6,000 was spent during the influenza outbreak in payment of physicians and nurses. The entire expense of the board for the year will exceed $8,000.——Dr. Charles B. Sitgreaves, Pemberton, has been appointed medical superintendent of the Burlington County Tuberculosis Sanatorium, New Lisbon, to succeed Dr. Daniel F. Remer, Mount Holly.

MASSACHUSETTS

East Boston Physicians Meet.—At the fifth annual meeting of the East Boston Medical Society, Dr. Frank H. Tilton was elected president; Dr. Robert Bonney, vice president; Dr. J. Danforth Taylor, secretary, and Dr. Alexander L. McLaren, treasurer, all of Boston.

Personal.—Dr. Frank G. Wheatley, North Abington, has been appointed a member of the board of trustees of the Massachusetts School for Feeble-Minded.——Dr. W. Edward Balmer, Whitinsville, has been nominated medical examiner (coroner) for the seventh Worcester District to succeed Dr. William L. Johnson, Uxbridge, resigned.

NEBRASKA

New Dodge County Officers.—At the annual meeting of the Dodge County Medical Society, held in Fremont, Dr. Albert E. Buchanan, Fremont, was elected president, Dr. Albert E. Hoff, North Bend, vice president, and Dr. Charlotte P. Siever, Fremont, secretary-treasurer.

Personal.—Dr. Hall H. Humphrey, Daykin, has been appointed a member of the Board of Medical Examiners of the state board of health, succeeding Dr. William T. Johnson, Pawnee City, deceased.——Dr. Charles E. Hershman, Alliance, has been appointed state surgeon of the Burlington System.

Hospital Items.—Mrs. Margaret A. Henry, wife of Dr. Edwin C. Henry, Omaha, has purchased two lots at Twenty-Sixth and Dewey streets, on which she will erect a new Lord Lister Hospital, three or four stories in height, with accommodation for 125 to 150 patients. The building will be ready by the end of the year.——The Methodist Hospital, Omaha, has purchased the house of Mrs. T. T. Northwall for $10,000.——The board of trustees of St. Luke's Hospital, Kearney, has purchased a new site for a building, and expects to break ground for the erection of a new building for the institution, to cost $50,000.

NEW MEXICO

Personal.—Dr. Leo L. Cahill, Springer, is seriously ill and under treatment at Miner's Hospital, Raton.——Dr. Charles M. Yater, Roswell, has been appointed health officer of Chaves County.——At the annual meeting of the New Mexico Public Health Association held in Albuquerque, Dr. Oliver T. Hyde, Albuquerque, was elected first vice president; Dr. Frank N. Carrier, Santa Rita, secretary, and Drs. Robert C. Kirkwood, Major, M. C., U. S. Army, Fort Bayard; Walter E. Kaser, East Las Vegas; James N. Massie, Santa Fe, and William F. Wittwer, Los Lunas, were elected directors.

Public Health Needs of the State.—Surg. John W. Kerr, U. S. P. H. S., as the result of an exhaustive study of public health conditions in New Mexico, details the personnel and expenditure required in his opinion properly to protect the health of the people of the state. This includes a health council composed of physicians and laymen and a state department of health with adequate appropriations to carry on the work; commissioner of health with a sanitary commissioner, bacteriologist and laboratory; vital statistician; supervising public health nurse, and such clerical assistance as may be necessary. He estimates that the state could easily afford to devote $50,000 a year to health work.

NEW YORK

Personal.—Dr. W. A. Matlick, Buffalo, has been appointed superintendent of the Aitken-Crow Wing Counties Tuberculosis Sanatorium, near Deerwood, Minn.——Dr. Julius Dworetzky, Staten Island, formerly of the sanatorium at Otisville and Sea View Hospital, announced that he has returned from France and will resume practice at Liberty.

Bill to Put State in Dairy Business.—An amendment to the Cotillo bill, aimed at the distributor's-producer's milk trust, has been framed for introduction into the legislature. It proposes a state commission to deal with the milk problem with authority to spend $250,000 or more yearly to establish agencies for the distribution and sale of milk at fair prices.

Enforcing Narcotic Drug Control.—Plans for the enforcement of the narcotic drug law, which went into effect February 1, were recently formulated at a conference of deputies of the Department of Narcotic Drug Control. The department intends to have its representatives visit every person or institution authorized to possess, dispense or prescribe habit-forming drugs to ascertain if their records comply with the law, and in case of violation to enforce the law and take steps to have the offender punished. Blanks have been sent to 3,000 persons affected by the law. The Department of Drug Control sent a communication to the New York County Medical Society stating that it realized that many of the narcotic drug problems were administrative, educational and medical rather than legislative, as was most clearly shown by the testimony brought out at the hearings of the legislative investigating commission. The commission therefore wished so to administer the law that the honest physician would be hampered as little as possible in the care and treatment of drug addicts and other patients. The commission also announces that its purpose is to administer the law in a spirit of helpfulness to the unfortunate drug addicts and to put them under such care and restriction that the growing evil of narcotic drug addiction may be effectually checked. The commission earnestly requests the cooperation and assistance of the medical societies of the state in restraining certain well known evils and abuses that existed among some of those legally entitled to possess and dispense narcotic drugs, and invites both medical organizations as such and physicians as individuals to consult freely with the department and to offer either suggestions or advice.

New York City

Ask Copeland's Resignation.—At a meeting of the representatives of more than sixty New Y[illegible] January 20, the action of Health ([illegible] Copeland in separating the division of industrial hygiene from the bureau of preventable diseases was condemned. Demands were made for Dr. Copeland's resignation and for the investigation of his whole bureau by the board of aldermen and by the state legislature.

Personal.—Richard Derby, Jr., Major, M. C., U. S. Army, who has been serving with a medical unit in France, has returned to this country.——Dr. Dudley D. Roberts has been released from military service and has resumed his practice in Brooklyn.——Charles White Berry, Lieutenant-Colonel, M. C., N. G., N. Y., Brooklyn, has been appointed adjutant-general of the state.——Dr. Smith Ely Jelliffe has retired from the editorship of the *New York Medical Journal.*

To Extend Industrial Hygiene Work.—As the result of a conference held by the health commissioner, Dr. Royal S. Copeland, and representatives of the labor sanitation conference, plans have been announced for the extension of the health department's work in industrial hygiene. The work is to be extended to new fields of industry, including stone and marble cutters, lithographers, printers, painters and the shipbuilding industry. The board of estimate has consented to make the money for this work available at once, and Dr. Copeland has appointed ten temporary medical inspectors and fifteen temporary sanitary inspectors to begin work immediately.

Gift to Broad Street Hospital.—An anonymous donor has agreed to give $100,000 to the Broad Street Hospital with the provision that the balance of $200,000 needed for the erection of an addition to the hospital be raised by March 1, 1919. This hospital, which has been in operation only since September, 1917, had to increase its facilities within three months after opening its doors by leasing the entire adjoining building. Admirers of the late Col. Theodore Roosevelt have pledged themselves, as a memorial to him, to endow an elaborate suite of rooms in the new addition. Up to the present time $60,000 has been contributed, and the two buildings adjoining the hospital have been purchased and are being held in trust for expansion.

NORTH CAROLINA

Personal.—Dr. Edgar L. Sutherland, Dublin, Va., is reported to be seriously ill with bronchial pneumonia.——Dr. James E. Kerr, Lilesville, and Julian D. Maynard, Wadesboro, have been made members of the Waynesboro Board of Health.

New Officers.—At the annual meeting of the Buncombe County Medical Society, held in Asheville, the following officers were elected: president, Dr. Charles D. Colby; vice president, Dr. James M. Lynch, and secretary-treasurer, Dr. John W. Huston, all of Asheville. It was reported that twenty-five members of the society either were at present or have been in the military service of the United States.

County Health Organization.—The progress of county health work in the state is encouraging. At present sixteen counties embracing a total population of 687,634, or 28.5 per cent. of the entire population of the state, have well developed and active health organizations. Of these sixteen counties, nine have furnished a summary of their work, which includes the construction of 7,364 sanitary closets, the examination of 20,834 individuals for hookworm disease, and the treatment of 3,928 persons for this disease; the visiting of 479 schools by health officers; the examination of 38,969 schoolchildren by their teachers, and of 12,699 by the health officers; the treatment of 6,171 children for physical defects; the physical examination of 1,528 adults by health officers; the inoculation of 37,324 persons against typhoid fever; the vaccination of 6,450 against smallpox; the quarantining of 4,356 cases of infectious diseases; the holding of 696 public health meetings, with an attendance of 87,450, and the preparation of 815 articles dealing with health subjects for the county papers.

OREGON

State Board Budget.—The state board of health has asked the legislature to appropriate $47,500 for the coming biennium. The plan proposed provides for an executive office, with a state health officer at its head, a bureau of vital statistics, a bureau of preventable diseases, a bureau of hygiene and sanitation, a bureau of laboratory work, apparatus, and in addition, a general expense item of $4,700.

Personal.—Dr. Leon Wolff has resigned as deputy city health officer of Portland, and has been succeeded by Dr. Ernest N. Crockett, Portland, who has recently returned from military service.——Dr. Estella Ford Warner, Portland, has been appointed director of social hygiene and physical education of the Young Women's Christian Association in Russia, and sailed for Archangel, Russia, January 22.——Dr. Seth M. Kerron has been appointed to succeed Dr. Waldo L. Cheshire as health officer of Eugene and in addition will act as school health officer.——Dr. Edgar O. Dutro, Hood River, deputy state health officer, has resigned.

Influenza.—In Portland, January 19, it was believed that the epidemic of influenza had been checked, though there were 204 new cases reported the previous day, with seven deaths. During the previous week 1,850 new cases had been reported, with a total of 115 deaths reported, though some of the deaths belonged to the previous week's record. Lieutenant-Colonel MacGruder of the United States Public Health Service, who has been in charge of sanitation in extracantonment zones on the Pacific Coast and who was sent by Surgeon-General Blue to help combat the epidemic, is quoted as being strongly in favor of the universal wearing of well made masks as a preventive measure, in connection with the other repressive measures that have been in force. To accommodate the large number of patients, barracks were erected at the Multonomah County Hospital. The cubital system of segregation of influenza patients was adopted in all Portland hospitals beginning with the date mentioned. To January 24, the total number of cases reported to the state health department since October 13 was 16,355; the total number of deaths 1,151. The total number of cases since January 1 was 4,719, and the number of deaths 307. The number of cases reported January 23 was 102, with twenty deaths. Dr. E. A. Sommer, director-general of the organization fighting influenza in Multonomah County, says that stronger state health laws with power of enforcement are needed to combat such epidemics.

PENNSYLVANIA

Semicentennial of Society.—The Medical Society of Franklin County celebrated its fiftieth anniversary, January 21, with a dinner at Chambersburg. There is only one of the charter members of the society still living, Dr. J. Burns Amberson, Waynesboro, who was unable to be present. The [illegible] were elected: president, Dr. Samuel D. [illegible]; vice presidents, Drs. Joseph P. Maclay, Chambersburg, and LeRoy H. Saxe, Fannettsburg; secretary, Dr. John J. Coffman, Scotland (reelected), and assistant secretary and treasurer, Dr. Frank N. Emmert, Chambersburg.

Personal.—After ten years of official connection with the department of health of Pennsylvania, during the last year of which he served as acting commissioner of health, Dr. B. Franklin Royer, Harrisburg, has reentered civil practice.——Dr. Charles E. Hays, Johnstown, was elected president of the state board of the Anti-Saloon League at its annual meeting in Harrisburg, January 22.——The resignation of George H. McConnon, Captain, M. C., P. M., Wilkes-Barre, has been accepted under date of Dec. 16, 1918.——The leave of absence granted Samuel H. Heller, Captain, Sanitary Detachment, First Infantry, P. R. M., Lancaster, has been extended from January 12 to April 12.

Philadelphia

Influenza Declining.—During the week which ended at noon, January 31, 614 new cases of influenza were reported to the bureau of health, as compared with 792 cases in the previous week.

MEDICAL NEWS

Election.—The Philadelphia County Medical Society at its annual meeting, January 15, elected Dr. B. Franklin Stahl, president; Dr. John W. West, vice president; Dr. J. Morton Boice, secretary, and Dr. Edward A. Shumway, treasurer.

Officers Elected.—At the last meeting of the Northern Medical Society, the following officers were elected for the ensuing year: president, Dr. Irwin S. Meyerhoff; vice president, Dr. Louis Jurist; secretary, Dr. Mulford K. Fisher; treasurer, Dr. John W. Millick, and corresponding secretary, Dr. David Nussbaum.

Personal.—Dr. Laura Hunt has returned after nine months of service in France in the laryngological department of the children's bureau of the Red Cross.——William H. Walsh, Lieutenant-Colonel, M. C., U. S. Army, has been made chief medical director of the Great Children's Hospital to be established at Mons, Belgium.

Italian Hospital Founded.—The founding of an Italian hospital in the vicinity of Sixty-Fifth and Vine streets, and the announcement that a prominent Italian had given $50,000 toward the project, was made public at a dinner at the Adelphi, January 30, given by the Italian residents of the thirty-fourth ward to the physicians, nurses and other members of the thirty-fourth ward influenza board for their faithful, unselfish and heroic services at the time the influenza epidemic was raging.

WASHINGTON

Personal.—Dr. Edward F. Hixon, Vancouver, who has been seriously ill for several months, is reported to be improved.——Dr. Stanley H. Titus, Spokane, who has been ill with pneumonia, is convalescent.——Dr. Alice M. Smith, Tacoma, has been made a fellow of the North British Academy and a member of its honorary council.

WISCONSIN

Proposes Vaccinating Legislators Against Influenza.—Dr. C. A. Harper of the state board of health, in his report to the finance committee of the legislature asking for appropriations for the present year, suggests that the members of the legislature be vaccinated against influenza and pneumonia with the government lipovaccines, as an example or test of the efficacy of the vaccines, and that the people generally be vaccinated against influenza, which he says is by no means past the danger point in the state. Appropriations are asked for the work of the board in the amounts of $55,000, which includes $5,000 for child welfare work and $5,000 for work against contagious diseases. An additional appropriation of $25,000 is also asked to combat venereal diseases, to equal the $25,000 appropriation of funds for this purpose from the federal government.

CANADA

New Psychiatric Hospital.—A new military hospital for mental diseases is to be established at London, Ont. The plans call for six ward buildings and one administrative building. The hospital will not be used for nervous cases, as mental and nervous cases are kept separate.

Queen's University.—January 29, Queen's University graduated a large class in medicine, the largest in the history of that institution. A number of the graduates of this last war session are medical students who served overseas in various capacities, but principally with the Queen's Hospital Corps in Egypt and France.

Personal.—Dr. James F. Cattermole, assistant superintendent of the Hospital for Epileptics, Woodstock, Ont., has resigned.——Capt. Benjamin Lyon, C. A. M. C., Kingston, Ont., has been awarded the Military Cross.——Capt. Walter W. Wright has returned to Toronto from overseas and resumed practice.——Surgeon-Probationer Graham Chambers, Toronto (1920), is on H. M. S. *Badger*, which was recently at Constantinople and was proceeding to Sebastopol.

Influenza in Quebec.—In the legislature of Quebec, the leader of the opposition, Mr. Arthur Sauve, recently expressed himself as not being satisfied with the steps taken by the board of health of that province to check the Spanish influenza which still exists in many parts of the province. He thinks that the board of health started too late when the epidemic struck that province. The prime minister, Sir Lomer Gouin, strongly defended the board and said that great devotion had been shown by the physicians and nurses of the province, and that the board of health was showing the same diligence today as it had at the outbreak of the disease and had continued to do throughout its course.

GENERAL

Laryngologists to Meet.—The annual meeting of the Middle Section of the American Laryngological, Rhinological and Otological Society will be held at Chicago, February 22, under the chairmanship of Dr. Otto J. Stein.

Personal.—Major-Gen. William C. Gorgas, U. S. Army, retired, will return from Guatemala to Washington, D. C., early in February, and on his return to South America in the spring will be accompanied by Mrs. Gorgas.——Rear Admiral Robert M. Kennedy, M. C., U. S. Navy, in command of the Naval Hospital, Washington, D. C., was operated on for intestinal disease, January 7.——Lieut.-Col. Herbert A. Arnold, M. C., N. G., Pa., retired, Ardmore, Pa., was elected surgeon of the Pennsylvania Commandery of the Military Order of Foreign Wars at its annual meeting, January 14.

Progress of Venereal Disease Work.—The division of venereal disease, United States Public Health Service, is conducting throughout the country approximately 175 clinics. During the period from Nov. 15 to Dec. 15, 1918, there was a total of 19,456 visits to twenty-nine clinics, or an average daily attendance of 38.1 at each clinic. There were 2,489 new cases, which was an increase of 188 cases over the preceding month. A total of 25,543 treatments were administered and 11,195 cases were remaining under treatment in the clinics, hospitals, and detention homes on December 15. As a result of 1,845 "follow-up visits" made by the clinic nurses and social workers, there were 1,070 visits to the clinics.

To Inspect Home Hospitals.—With the authorization and approval of Surgeon-General Ireland of the Army, an official committee of the National Red Cross has begun a tour of inspection of the forty-three general hospitals throughout the country where wounded American fighting men are receiving care. Debarkation hospitals where wounded soldiers, marines and sailors are being received from overseas are being visited first. The object of the inspection is to improve the service of the Red Cross wherever possible. The committee is headed by Col. C. H. Connor, assistant general director of military relief and chairman of the Medical Advisory Committee. The other members are lay men and women.

American Woman's Hospital Helps Serbia.—At a recent meeting of the American Woman's Hospitals, Madame Grouitch, wife of the Serbian minister and herself a commissioner of the Serbian government, told of the great need of physicians in Serbia. There are only 140 Serbian physicians left; all the rest have been killed in war or have died of disease. The Serbian unit of the American Red Cross, which will leave for work in Serbia as soon as passports can be obtained, includes Dr. Minnie C. O'Brien, San Antonio, Texas; Dr. Marjorie B. Burnham, Kinsman, Ohio; Dr. Katherine M. Cook, New Wilmington, Pa.; Dr. Mary H. Elliott, Holly Springs, Miss.; Dr. Alberta F. M. Greene, Fergus Falls, Minn.; Dr. Lulu Hunt Peters, Los Angeles; Dr. Helen T. Rattermann, Cincinnati; Dr. Harriet M. Gervais, Dorchester, Mass.; Dr. Sarah Elizabeth Foulks, Davenport, Iowa.; Dr. Edna Ward, Denver, and Dr. Marie Hyndman, New York. At this meeting it was announced that an ambulance had been given to the American Woman's Hospitals by the Patriotic Penny and National Special Aid Society of Wilmington, Del. Major Gibson, manager of the Red Cross in France, has allowed $50,000 for the maintenance of the society's hospital at Luzancy. Gifts amounting to about $2,500 from donors in this country were also announced.

Bequests and Donations.—The following bequests and donations have recently been announced:

Presbyterian Hospital, New York City, $5,000 by the will of Elizabeth H. Keyes.

Germantown Hospital and Dispensary and Chestnut Hill Day Nursery, Philadelphia, each $1,000 by the will of Sarah R. Watson.

Relief Work in Siberia, an appropriation of $200,000 by the American Red Cross.

Soldiers and Sailors' Hospital, at Boehne Camp, Evansville, Ind., a donation of $1,300 by Mrs. Sallie H. Roots, Evansville, in memory of her parents, for the equipment of one of the new wards.

Johns Hopkins University, Baltimore, $200,000, for the building and equipment of a laboratory or building devoted to the technical arts, or, if more desirable, for the erection of University Library Building, by the will of Eugene G. Mergenthaler.

Lock Haven, Pa., Hospital, a donation of three $1,000 U. S. Liberty Bonds by Farmer Stewart as a memorial to his deceased wife.

Home for Incurables or Home for Aged and Infirm under the auspices of the Philadelphia Federation of Jewish Charities, a trust fund of $20,000 created by the late Rose Rice, on the decease of two sisters, as a memorial to Amelia Rice.

Mount Sinai Hospital, New York City, $15,000; Hebrew Orphan Asylum, United Hebrew Charities, Home for Aged and Infirmed Hebrews, and Hebrew Infant Asylum, each $10,000; Lebanon Hospital,

$5,000, and St. Vincent's and Presbyterian Hospitals, each $2,500, by the will of Benjamin Blumenthal.

Mount Sinai and Women's Hospital, New York City, and Middlesex Hospital, London, England, each $5,000, by the will of Henry Joseph Duveen.

Cornell University, Ithaca, N. Y., $5,000, by the will of Dr. William Mecklenburg Polk, New York City.

Marine Hospitals for Care of Discharged Disabled Soldiers and Sailors.—Under an arrangement suggested by the War Risk Insurance Bureau and made by the Public Health Service, if approved by Congress and an appropriation made, soldiers, sailors, marines and others discharged from military service with disease or injuries contracted in the service will be cared for in the marine hospitals of the United States Public Health Service. At present the War Risk Insurance Bureau under the law creating it and the regulations governing it is responsible for the care of 1,724 beneficiaries who require medical or surgical treatment. Within a short time it is expected that provision will have to be made for at least 24,500 men discharged from the service on account of tuberculosis, and for 50,000 cases of psychoneurosis, epilepsy and other nervous ailments. The plan, which is now before Congress, is to empower the Public Health Service to increase the present capacity of the twenty-two marine hospitals of 1,689 beds, to 5,208 beds, and to provide an additional 2,450 beds in new hospitals and sanatoriums to be built in various parts of the country. A suggestion to make the 150 small Army posts scattered throughout the United States hospitals for the care of these men is not deemed feasible or desirable. The plan now proposed and under consideration would, it is believed, have the advantages of a minimum of outlay for overhead construction and administration, favorable location near large cities, employment of a hospital organization with long and successful practical experience, and finally, the fact that the War Risk Insurance Bureau and the Public Health Service are both parts of the Treasury Department, thus permitting the closest possible coordination of activities.

FOREIGN

Death of Bang.—The micromethod test for sugar in the blood has carried to every country the name of Dr. Ivar Bang, professor of physiologic chemistry at the University of Lund. News has just been received of his sudden death while at work in his laboratory.

Fight Typhus in Siberia.—The American Red Cross announced that an antityphus train, the control of which is under the American Red Cross Commission and which is operated by the American Red Cross, is to be sent through Siberia to fight the typhus situation, which has been very grave. The train is composed of fourteen cars, including a car with bathing facilities, cars for clothing, drugs, and for personnel. The train will act as sort of standard bearer. On coming to towns where typhus prevails, the cooperation of local authorities, hospitals and physicians will be obtained, and the work done as far as possible through the Russian people themselves. Circulars printed in Russian will be distributed along the line, informing the people of the necessity of bathing and keeping clean and detailing the chief precautions against typhus.

SOUTH AND CENTRAL AMERICA, MEXICO AND WEST INDIES

Deaths in the Profession.—Recent exchanges from Brazil bring a long list of physicians who have been victims of influenza. Among them are Dr. **T. Bayma**, the distinguished physician and bacteriologist of S. Paulo, director of the bacteriologic and the vaccine institutes there, aged 55. His writings on tropical medicine and hygiene have frequently been summarized in The Journal, and he presented seven important communications to the recent South-American Congress of Microbiology.——Dr. **Santos Moreira**, a leading pediatrist of Rio de Janeiro, secretary of the Sociedad Brazileira de Pediatria, director of the *Medicina Clinica* and frequent contributor to journals on children's discases.——Dr. **Paulo Silva Araujo**, a leading microbiologist who studied under Wright in England and under Ehrlich in Germany, and in 1915 published his "Vaccine Therapy of Bronchial Asthma." The clinical laboratory founded by him turned out high grade organotherapeutic products and, among others, isolated the *Bacillus bulgaricus* in Brazil.——The *Brazil Medico* of November 2 gives the names of fourteen other physicians who had succumbed at that early date to the epidemic, including Dr. **S. B. Montenegro**. Nearly all were in the very prime of youth and health.——The death is also reported at Buenos Aires of Dr. **E. Diana**, a popular pediatrist.

CORRECTIONS

Discussion on the Face Mask.—In the report of the proceedings of the American Public Health Association (The Journal, December 28, page 2174) a short discussion is credited to Dr. W. H. Kellogg, secretary of the California State Board of Health. Dr. Kellogg writes that the statement published did not represent what he said. Most of Dr. Kellogg's discussion referred to charts which he exhibited and which could not be reproduced in connection with the abstract sent in by the reporter. A more complete copy of the discussion follows:

Dr. W. H. Kellogg, San Francisco: I shall confine the few remarks I have to make to the subject of the wearing of gauze masks because I am more or less familiar with this phase of the prevention of the spread of influenza by reason of having come from California where this method has been given the most thorough trial. The people of San Francisco put on gauze masks by an ordinance that was enforced very thoroughly, and they wore these masks on the streets during the time this ordinance was in effect. I have always believed very strongly in the possibilities for the prevention of droplet-borne infections by means of the use of the gauze mask, but I am sorry to say, I have not the same confidence now that I formerly had. It used to be my custom to tell medical students that if they put gauze masks on all people for a period of two or three weeks, all the droplet-borne infection would probably be abolished, but I no longer believe that.

In the determination of the value of a measure such as this, the only way by which we can arrive at any rational conclusion is to compare the experiences of cities that have used the measure and those that have not. The mistake has been made by some of our ardent advocates of considering only the experience of San Francisco and look at the curve of the deaths or of the cases and note there was a rapid decline from the moment the masks were put on the people.

(On a chart which was exhibited it was shown that the curve for San Francisco resembled closely that of Washington and Chicago, but that Los Angeles differed.)

It has been thought by some people in San Francisco that the experience of Los Angeles has proved that the mask did the business for San Francisco, and that Los Angeles is having a bad time because it did not wear the mask. The state board of health was importuned to put the mask on Los Angeles, but the evidence was not such as to warrant a move of this kind.

These curves (referring to chart) are the deaths and in Los Angeles you will note that the curve is sharper than it is in San Francisco. But against the curve of Los Angeles I have on the other charts the cities of Washington and of Buffalo, which are practically the same size, and of Philadelphia, which is much larger, and so far as I know, there are no cities in the list that put on the masks to the same extent that San Francisco did. Of the forty cities, the figures for which are published in the United States Census Bureau list, 13 had a higher mortality rate than San Francisco; 26 had a lower mortality rate, so that we have two things to consider in comparing these cities, one of which is the shape of the curve and the duration of the epidemic. It is to be noted that the period of time is about the same for all of them from the beginning to the end. That is one point in which San Francisco shows no difference over the others. Another is the number of deaths resulting from the disease. San Francisco had a death rate of 4.7 per 1,000, whereas Los Angeles, which apparently suffers by comparison on the chart, had a death rate of 3.3 per cent.; Chicago 3.5 per cent., etc.

As to the reasons for the failure of the mask which theoretically should be such a valuable thing, there are a number of things to my mind to account for that. If the mask is properly made it affords an efficient protection against droplet-borne infections. Many of the masks used were not properly made; they were made of too light gauze and of too few layers, many of them, to comply with the law. Again, people did not wear masks in the places where they were needed most, where people entered into associations with ill relatives and office associates. In the banks, when the curtains were pulled down, the clerks took off their masks and got busy over their books, so that there was every chance, according to the theories of droplet-borne infections, for the disease to travel from one to the other. Therefore, the measure does not appear to me to be worthy of consideration.

I am growing doubtful as to the value of the mask as a protection to the individual who understands what he is doing. San Francisco Hospital had an incidence of infection of 78 per cent. among the trained nurses which could not be accounted for by the fact that they took the masks off when in association with patients. If that were the cause of the infection, it would confirm the usual incidence among the general population, but such a high rate was to be accounted for only by the fact that they got their infection from patients themselves in spite of the fact that they were wearing properly made gauze masks.

Abdominal Hysterotomy.—We are informed by Dr. E. G. Zinke that an error occurred in the abstract of his paper on "Limitations of Cesarean Section," published in The Journal for Jan. 18, 1919, page 220, second column, tenth line from the bottom. The words "abdominal hysterectomy" should read "abdominal hysterotomy."

MEXICO LETTER

Mexico City, Jan. 26, 1919.

The Typhus Congress

The Congreso Nacional del Tabardillo closed its sessions January 21 after a week of discussion which seems destined to bear fruit. About 135 physicians registered for the meeting, and thirty-four communications were presented relating to the history of Mexican typhus, its etiology, symptomatology, treatment, prophylaxis and epidemiology. Practitioners came from all parts of the republic to take part in the discussions, even from the remotest states.

Two articles were read which sustained the assumption of the important part played by Plotz' *B. typhi exanthematici* in the development of the disease, but the predominant opinion was that it had not been proved that this bacillus was the specific germ of the disease. The observations of Muratet, Ceconi and Fraenkel on the importance of the provoked exanthem in differentiation were cited, and it was urged that observations to confirm this should be compiled.

TREATMENT

In treatment of the disease, the antityphus serum prepared by Nicolle and Blaizot was the main topic discussed, and it was deplored that it had not been possible as yet to prepare it in Mexico nor obtain it from the United States (our usual source of supply for therapeutic serums), as to date we have not learned that it is yet made in our neighbor nation. Besides the scientific interest of the matter, it has commercial interest as well, which perhaps the manufacturers of biologic products will not overlook. As Mexican typhus is endemic throughout the central tableland of the country, there would be a great demand for the said serum, especially if the favorable results which the French investigators are said to have realized from its use are confirmed by others.

RESEARCH ON TYPHUS

A permanent committee was appointed to carry on research on typhus—which still has many points insufficiently cleared up—and to organize the next congress which will convene in the City of Mexico in 1921. The proposal, by Dr. A. B. Vasconcelos, to found a special institute for experimental study of tabardillo was approved, relying on private benevolence for the purpose. Although it was recognized that the present moment is not very propitious for such an undertaking, yet the possibility was recognized that some rich and philanthropic citizen or citizens of the United States might prove willing to invest mony in this way as it would redound to the benefit of humanity and would contribute to draw still closer the bonds of friendship between the two neighboring peoples, which is the ideal cherished by various leading minds among the Mexicans. The committee of organization for the next typhus congress includes Dr. Alfonso Pruneda as president and Dr. R. E. Cicero as secretary. The address of the latter is 2/a calle de las Moras, No. 34, Mexico City.

Official Campaign Against Syphilis

The Departamento de Salubridad, the national public health authority, has decreed that in future the candidate for matrimony must present a certificate which asserts that the Wassermann seroreaction with the blood of the candidate has given negative results. Those persons who reside at points where there are no laboratory facilities will comply with this formality by presenting a certificate based on the clinical investigation and equally negative. As a further measure, physicians are required to inform the departamento of all their syphilitic patients who have abandoned treatment before they have been cured as radically as is possible.

Inherited Syphilis at Puebla

We are informed from this neighboring city that during the month of December last there were thirty-one deaths from inherited syphilis. This is the largest number ever recorded for a single month, and it indicates the increasing prevalence of syphilis in that community.

British War Relief Work

The British Women War Workers Society of this city presented a favorable balance sheet at the close of the year. According to this, they had collected more than 14,000 pesos, almost all of which was invested in the war relief work done by the society; 221 sweaters, 790 pairs of socks, and a large number of cotton articles were forwarded to Europe.

Association for Prevention of Blindness

This beneficent association is soon to open a free consulting dispensary for persons with anything wrong with their eyes. In connection there will be an optician's establishment. In order to accomplish this high aim, an appeal was made to charitable persons and they succeeded in collecting the sum of 8,000 pesos from private parties, with which they have started the work. The association accepts with gratitude any cash donations which any one may make to aid the work of the consultorio. The official title of the association is the Asociacion par evitar la Ceguera en Mexico, and its post office address is Apartado 5331, Mexico, D. F.

Proposed Roadway Between Mexico City and El Paso

A project is under discussion for the construction of a roadway to connect this city with El Paso (Texas) which would permit, if realized, automobile travel between the two countries. There is a plan to form a company which will supply the necessary capital, and they have asked for the concession from the authorities.

The Spanish Edition of The Journal

I have been able to ascertain that the first number of the Spanish edition of The Journal has made a very good impression on the profession in Mexico on account of the value of its original articles as well as by the wealth of information which it contains.

Personal

Dr. Rafael Cepeda has been appointed presidente municipal of the City of Mexico, and Dr. F. Bello, a prominent internist, has been appointed to a similar position in the neighboring city of Puebla. Dr. Bello has announced that he will turn back into the municipal treasury the salary to which he is entitled, as long as he holds the position.

The Cold Wave

The cold was intense here from January 22 to 24; we are not accustomed to such cold weather. It is known that two children died in consequence of sleeping in the extreme cold, and three pedestrians were buried by the snow on the road to Toluca.

LONDON LETTER

London, Jan. 7, 1919.

The Prevention of Venereal Disease

The apprehended danger of the increase of venereal disease as a consequence of demobilization has been referred to in these letters. A controversy that would have been impossible only a few years ago, when the subject of venereal disease was treated with reticence in the lay press, has taken place in the *Times*. A number of the leaders of the profession, including Osler, Ferrier, Rickman Godlee, and Mott, published a joint letter urging, in view of the daily increasing menace, that "timid and hesitating counsels should give place to clear advice and strong purpose. Extraneous considerations can have no place in sanitary problems; it is because they have had too much place that the National Council for Combating Venereal Diseases has failed. Smallpox and typhoid have been largely banished by measures based on knowledge of these diseases. Venereal diseases should be similarly dealt with. It has been abundantly proved during the war that they can be controlled by simple sanitary measures, the success of which is striking, and the materials for which can be obtained from any pharmacist. These measures should at once be made known, and available and organized instruction given in their application. This is the *only* effective method of meeting a dangerous situation—dangerous not only for our soldiers and sailors, but for the population at large."

To this criticism the president, vice president (Sir Thomas Barlow) and chairman of the National Council for Combating Venereal Disease replied that "while the council has taken full cognizance of all available scientific knowledge, it has deliberately decided against advocating the particular methods apparently suggested by the writers. The panacea is a wholesale distribution of prophylactic packets. The policy of the national council since 1916 has been early preventive treatment. Since July, 1918, it has pressed the same policy on the government and on the civilian population, and it is now in process of being organized throughout the country. The former course was denounced in scathing language by the secretary of the navy when America entered the war. The latter is now being vigorously carried out by the American medical authorities, experience having powerfully attested its efficacy. The success claimed by Sir William Osler and his associates for their procedure has been at least equaled by that advocated by the national council, and this question cannot be discussed without taking into account the special facilities that exist whenever forces under discipline are being dealt with. The national council is not only concerned with combating disease in the armed forces but is striving to avert the peril on demobilization. Measures that can be applied to disciplined bodies may be absolutely impracticable in dealing with the general community. 'Extraneous considerations,' which the signatories lightly dismiss, and sentiment, which may exert a dominant influence on public opinion, cannot be disregarded. It is easy for distinguished scientists to lay down 'simple sanitary measures,' but the question resolves itself into administrative measures required on a large scale throughout the country, and here the difficulties begin. You cannot administer in such intimate matters without the intelligent acquiescence of the people. The unanimous opinion of sixty health officers of counties and large towns cannot be ignored. 'We are strongly of the opinion,' they state, 'that not only would the official distribution of prophylactic outfits to the civil population lead to moral deterioration of the nation, but it would not materially diminish the prevalence of venereal diseases.' In dealing with human nature it is not always possible to conform to the letter of scientific law."

The controversy was continued by laymen who were evidently somewhat mystified as to the point at issue, though one wrote: "If the critical hour is, say, 11 p. m., the national council objects to the use of disinfectants at 10:45, but raises no objection to the treatment at 11:05. The sinner must not prepare for immorality, but he may use the best means known to science to escape its consequence." In a leading article the *Times* took up the question and informed its readers that "until recently there was no certain means of cure and no certain means of prevention of syphilis. Medical science has now provided us with both, and there is prospect that in a few years one of the most appalling scourges of modern life will be almost unknown. Syphilis can be prevented by the use of calomel before infection, and less certainly by its use within an hour or two of infection. Medical evidence indisputably supports the view of Sir William Osler and his cosignatories. A simple amendment of the venereal diseases act, 1917, is necessary, in order that the preventive medicine may be easily obtained under the necessary safeguards." Evidently from motives of delicacy, although deprecating that these should stand in the way of the public interest when the extinction of such a plague is attainable, the *Times* has used the word "medicine" for ointment. This has led laymen into the error that syphilis can be prevented by the internal administration of calomel.

Malaria in England

The measures taken by the medical departments of the army and the Local Government Board have been effective in preventing the spread of malaria in this country through the agency of soldiers returned from the eastern campaigns (the worst of the war areas as regards malaria) who are carriers of the parasite. Army malaria patients brought back from those countries were treated in the military hospitals, which reduced to small and manageable limits any risk of the spread of the disease, except in a few districts where there was evidence of malaria having been contracted locally, on account either of the presence there of a large number of malaria carriers, or the existence of anopheline mosquitoes. As shown in previous letters, indigenous cases of malaria have thus originated in England during the war. *Anopheles* mosquitoes are found to be present practically in any part of England where the conditions are favorable to their breeding. Even the demobilization of the army now in progress may lead to an increasing number of human carriers of the malaria parasite being spread throughout the country. Fresh measures to meet this situation are being devised by the medical department of the Local Government Board in the form of extended civil administration. The local authorities will be directed to add malaria to the list of diseases made compulsorily notifiable and to transmit at once information of such cases. The precautions to be taken with a view to preventing the spread of the disease will also be published, and government medical inspectors will at once visit any infected area.

The Treatment of Hydrophobia in England

About twenty-five years ago hydrophobia was completely stamped out of Great Britain by the compulsory muzzling of dogs—a procedure that aroused considerable opposition among dog fanciers. During the war, cases have occurred in the west of England. As the most stringent precautions in the form of quarantine are taken when dogs are imported, and have proved successful during the long period which has elapsed, it is supposed that the disease must have been introduced by dogs carried in aeroplanes. Arrangements have been made for specific antirabic treatment at Plymouth with materials supplied by the Pasteur Institute of Paris. When persons are bitten by dogs in areas in which rabies is suspected it is recommended that the wound be treated as soon as possible with undiluted phenol (carbolic acid) or some cresol preparation or similar disinfectant. The disinfectant should be allowed to come into contact with all parts of the wound, and should then be washed out with water or dilute disinfectant. If no disinfectant of the kind is available, the wound should be thoroughly washed and irrigated with hot or cold water. If the dog is pronounced on competent veterinary authority to have had rabies, the person bitten should be urged to secure specific antirabic treatment as soon as possible, no matter what local treatment has been applied.

Airmen's New Height Record

Capt. Andrew Lang and Lieutenant Blowes have broken the world's altitude record on a British-built and British-engined biplane, flying at Martlesham, near Ipswich. The altitude attained was 30,500 feet, the time taken being 66 minutes and 15 seconds. Through a fault in the oxygen apparatus, Lieutenant Blowes collapsed, and at 28,000 feet the heating apparatus began to work erratically. The machine was brought to a stop through the lack of gasoline pump pressure due to the rarefication of the air. Luckily, Captain Lang was able to descend slowly, and at 20,000 feet Lieutenant Blowes recovered consciousness. Captain Lang had made two previous attacks on the altitude record, which had been held by America. He is well known in Australian motoring circles, and in 1910 drove a motorcar across northern Australia for his government in an exploring expedition. Lieutenant Blowes is an experienced pilot, and in France brought down several German aeroplanes. Both officers suffered from frost-bite, and the observer had to go to the hospital suffering from two badly frozen hands and toes, while the pilot's face and fingers were frost-bitten.

PARIS LETTER

Paris, Jan. 9, 1919.

Early Treatment of Eye Injuries

At a recent meeting of the Académie de médecine, Dr. F. de Lapersonne, professor of clinical ophthalmology in the Paris medical faculty, reported the results he had obtained since July 15, 1918, in the treatment of eye injuries. At that time the large hospitals of Paris were regarded as evacuation hospitals, and, because of excellent transportation facilities, the wounded sent in from the front, were operated on in from twenty-four to forty-eight hours after being wounded. The doctor reported eighty-three cases of this sort in which operation was performed. Many of these patients had other injuries than those of the eyes, in fact, they had sustained multiple wounds, and had been operated on in the surgical service at the Hôtel Dieu.

In all of these cases, except three, the operation was performed under procain anesthesia, irrespective of the extent or degree of the intervention. When the roentgenogram showed the presence of a foreign body or of a fracture, de Lapersonne frequently resorted to orbitotomy, making a curved incision (following the rim of the bone) which gave free access to the orbit, at the same time ensuring the safety of the conjunctiva and the palpebral fissure. Immediate suture was the rule in all these early operations, suture of the conjunctiva after partial or complete ablation of the eyeball, suture of wounds of the eyelids with conservation of even the smallest shreds of tissue, suture of the circumorbital skin wounds, after removing blood clots, bone fragments and foreign bodies, and cleansing the wound. In some instances skin grafting had to be resorted to, using either a sliding or a pedicled flap, in order to cover over a denuded area. De Lapersonne insists that immediate suture of wounds should be the absolute rule in these cases of orbito-ocular wounds which come under the head of urgent surgery.

Treatment of Bone Fistulas

Dr. Auguste Broca recently discussed the statistics on bone fistulas, the result of war wounds, furnished the Société de chirurgie de Paris by Dr. G. Blanchard and by Drs. Dambrin and Montazard. It was interesting to note how Dr. Blanchard succeeded in obliterating the bone cavity resulting from the clearing out of all devitalized tissue in the fistula. At the time of operating, the cavity is treated according to the

Phelps' method (pure phenol, then 90 per cent. alcohol) and then packed with gauze wet with a mixture of phenol, balsam of Peru and spirits of camphor. The dressing is changed on the second or third day. The gauze plug is removed on the fifth day, and from then on the tamponade is made alternately with gauze wet with balsam of Peru and gauze wet with permanganate of potassium. On the tenth to the thirteenth day the bone is cleaned and secondary plombage is performed. Blanchard recommends for this filling a paste consisting of 150 gm. of paraffin; 15 gm. of balsam of Peru and 20 gm. of carbonate of bismuth. This paste, melted, is poured into the wound where it solidifies. Primarily, this is not regarded as a true plombage—to remain *in situ*, to become encysted—but as an internal dressing which is intended to prevent reinfection and which will eliminate itself gradually. The paste in place, secondary suture is done. The results are good, in the sense that a cure has been obtained, as a rule, in from two to four months, and it is possible that this time may be shortened.

Dr. Dambrin and Montazard called attention to the benefit from injection of methylene blue into the fistula (10 per cent. solution in a 5 per cent. solution of phenol or in a 4 per cent. solution of liquor formaldehydi) for the purpose of locating the more or less tortuous channels of the fistulas, and coloring the necrotic tissues, thus giving the operator needed information at the most opportune time. This procedure seems to be a very useful one.

On the other hand, they studied the effect of mineral waters—at the most famous watering places in the Pyrenees—and they found that the waters seemed to promote healing in the cases in which minor superficial lesions persisted, that is, in about 15 per cent. of cases. Sometimes these waters aided in verifying the permanency of the cure by provoking a "poussée" in the apparently healed area. The patients who seem to be most likely to benefit by these waters are those on whom an extensive operation has recently been performed. This treatment should be regarded as being only a supplementary one, to be carried out under the advice and control of an experienced surgeon.

Abdominal War Surgery

At a recent meeting of the Société de chirurgie de Paris, Professor Quénu discussed two reports made to the society on this subject, one by Dr. Caudrelier and the other by Drs. Maisonnet and Coulaud. Dr. Caudrelier divided his cases into two groups: (1) Those in which operation was performed as soon as the patient came under his care; (2) those cases (there were only 2) in which he operated later. There were 24 cases in the first group: 20 cases involved wounding of only one viscus (5 cases of wounds of the small intestine; 8 of the large intestine; one of the stomach; 3 of the liver; 3 of the bladder); in 3 cases several viscera were involved (2 cases of wounds of the large and small intestine; one case of wounds of the liver and the respiratory apparatus); one case of simple penetrating wound without any visceral lesion. Of these 24 cases, 18 were shell wounds and 6 were bullet wounds, and they were operated in from three to six hours after the wounding, most of them at the fifth hour; only one after nine hours. There were 9 deaths from peritonitis and hemorrhage in this series; 15 patients were cured. In the 2 cases in which Caudrelier did not operate immediately, he intervened later because of fever and local symptoms. In one of these cases he operated thirty-five hours after the patient had been wounded by a rifle bullet. He found a large hematoma, containing fetid material, behind the ascending colon. The latter was red, bleeding, but not perforated. This patient died a few days later.

Drs. Maisonnet and Coulaud made 100 observations, as follows: 33 patients were considered inoperable because of the gravity of their general condition; 42 patients were not operated on because they arrived too late or because of their satisfactory general condition in view of the nature of the wound; 17 patients were operated on although in a most desperate condition so as to give them some chance for recovery; 18 patients were in fairly normal condition when operated on.

The results obtained were: Among the 75 instances in which no operation was performed, there were 27 cures, 36 per cent.; among the 35 operated cases there were 11 cures, 31.4 per cent. At first glance, these two sets of statistics seem to be pretty much alike, with the odds slightly in favor of not operating. But Quénu showed, by an analysis of the cases operated, that among them, considered hypothetically as wounds of the abdomen and terminating in a spontaneous cure, were penetrating wounds of the abdomen alone, which should, therefore, be eliminated from the discussion. The principle of surgical intervention in penetrating wounds of the abdomen governs alike the cases seen in war and those seen in civil practice, and the statistics quoted by Maisonnet and Coulaud, in spite of the figures given, support this principle.

Using Soil to Combat Asphyxiating Gases

M. Daniel Berthelot recently stated before the Académie des Sciences that soil or earth can be used as a protection against asphyxiating gases. His researches demonstrated that white sand, either wet or dry, absorbs chlorin very poorly; hence it should not be used for this purpose. Yellow sand, containing iron, is preferable, although its gas absorbing power is not great; in fact it is a mediocre absorbant. On the other hand, ordinary soil, suitable for agricultural purposes, has a most remarkable fixating power for chlorin gas. This absorbing power, especially in the case of dry soil, may be increased two-fold by the addition of a few cubic centimeters of water; the addition of large quantities of water does not increase the absorbing power of the soil. This absorbing power is very manifest with earth containing about 10 per cent. of water, which is about the usual dampness in soil of this kind even in dry weather. It is only necessary to dig down a few centimeters in order to secure the soil containing the required moisture.

The Maimed Farmer

Many agriculturalists who have been maimed in the war are asking whether they will be able to support themselves by farm work in the districts whence they came. About 60 per cent. of these former farmers who have been maimed are not returning to farm work. This is a serious state of affairs for agriculture. Undoubtedly most of these men would be able to return to farming if they were supplied with suitable prostheses. They have only to be convinced of this. With that object in view, Dr. Louis Mourier, undersecretary of state for the Service de Santé militaire recently called together in one of the halls of the Grand Palais the wounded and maimed agriculturalists who were still under treatment in the hospitals of Paris, to show them moving pictures portraying maimed agriculturalists at work. The Service de la main-d'oeuvre agricole has published 50,000 copies of a pamphlet entitled "The Maimed Farmer" which will be distributed among the various sanitary formations for the purpose of showing these men the different kinds of work which they may take up in spite of their condition and also the profits from them. Centers will be established at which prosthetic appliances and apparatus will be on exhibition, together with machinery modified to meet individual needs. A commission will have charge of this work, so that every applicant, with but few exceptions, may secure apparatus properly adapted to his needs.

Demobilizing Medical Students

According to instructions given by Dr. Louis Mourier, undersecretary of state for the Service de Santé militaire, the medical students in the army are to be stationed at sanitary formations in university centers which will make it possible for the students to continue their studies. This arrangement applies to the students of medicine who have served with the colors for more than fifty-three months, that is, those who were incorporated before the mobilization; and also students who have served between fifty and fifty-three months and, who have served at least thirty-two months in an infantry regiment or as division stretcher bearers or who have been wounded.

Marriages

Charles Robert Henry, Lieut., M. C., U. S. Army, New York City, to Miss Addie Marsh Sparks, at Lafayette, Ga., Dec. 24, 1918.

John Simpson Crater, Lieut., M. C., U. S. Army, Bristol, Pa., to Miss Ethel Margaret Steidel of Jeddo, Pa., Dec. 24, 1918.

William Anthony Cooling to Miss Nora Murphy, both of Wilton, Iowa, at Des Moines, Iowa, Dec. 27, 1918.

James Hoyt Kerley, Lieut., M. C., U. S. N. R. F., to Miss Ethel Rae Johnson, both of Brooklyn, January 18.

James Welch Guest, Chicago, to Miss Sarah Pickette Lindsey of Memphis, Tenn., Dec. 28, 1918.

James H. Cotton, Toronto, to Mlle. Audric Rubanni, at Toronto, January 25.

Deaths

Howard Emerson Ames ⊕ **Medical Director, Capt., U. S. Navy (retired),** Washington, D. C.; University of Maryland, Baltimore, 1874; aged 68; who entered the Navy in 1875, and was a member of the Greeley Relief Expedition; was one of the first sent to Kingston, Jamaica, at the time of the earthquake, and was in command of the Chelsea Hospital, during the great fire in Boston; a member of the Association of Military Surgeons of the United States; whose last assignment to duty was at San Francisco, and who was retired for age on August 7, 1912; died in the U. S. Naval Hospital, Washington, December 27.

Andrew Culloden Panton ⊕ Portland, Ore.; University of Toronto, Ont., 1882; aged 62; one of the most prominent surgeons of the Pacific Northwest; for several years professor of anatomy and materia medicine in the University of Oregon, and for more than thirty years a member of the visiting staff of the Good Samaritan Hospital; chief surgeon of the Portland Railway Light and Power Company; a member and president of the State Board of Medical Examiners from 1904 to 1909; died at his home, January 18, from pneumonia following influenza.

Frederick Wilkinson Olcott ⊕ **P. A. Surg., Lieut., U. S. Navy (retired),** Washington, D. C.; College of Physicians and Surgeons in the City of New York, 1884; aged 57; who was retired as passed assistant surgeon in 1911, and by act of Congress was appointed, Feb. 13, 1911, to the rank held by him at the time of retirement and placed on the list of retired officers of the Navy, unlimited, on account of disability in line of duty; a patient at the Government Hospital for the Insane; died in that institution, January 26.

William Smith Lalor ⊕ Trenton, N. J.; University of Pennsylvania, Philadelphia, 1872; aged 70; in 1880 president of the medical societies of Trenton and Mercer County; city physician of Mercer County for six years; a school trustee and school superintendent each for three years; for seven years a member of the board of health, and for a long time vice president of the Interstate Fair Association; died suddenly at his home, January 18, from heart disease.

Charles Henry Riley, Baltimore; University of Maryland, Baltimore, 1880; aged 62; a member of the Medical and Chirurgical Faculty of Maryland; founder of and surgeon to the Woman's Hospital of Baltimore; professor of obstetrics in the Woman's Medical College of Baltimore; president of the board of trustees of the Sheppard and Enoch Pratt Hospital, Towson; died, January 23, from kidney disease following influenza.

Washington Berry Grove ⊕ **Medical Director, Capt., U. S. Navy;** University of Virginia, Charlottesville, 1896; aged 43; who entered the Navy in June, 1897, had been in command of the Norfolk (Va.) Hospital, as executive surgeon from October, 1915, to December, 1918, and had recently been assigned to the command of the U. S. Naval Hospital, Washington, D. C.; died in that institution, January 21.

Elmer Ellsworth Holt ⊕ **Capt., M. C., U. S. Army,** Mena, Ark.; Barnes Medical College, St. Louis, 1898; aged 51; who was on duty at Camp Jackson, Columbia, S. C., and was honorably discharged late in December, 1918, died at his home, January 23, from a gunshot wound, believed to have been self-inflicted, with suicidal intent, while temporarily deranged, as an after-effect of influenza.

Paul Carroll Dennett ⊕ **Lieut., M. C., U. S. Army,** Boston; Tufts College Medical School, Boston, 1916; aged 26; on duty with the 75th Coast Artillery Company, American Expeditionary Forces in France; was taken ill with influenza on the transport, and on his arrival was removed to Base Hospital No. 65, near Brest, where he died, October 16.

Edgar Cox ⊕ Kokomo, Ind.; Medical College of Ohio, Cincinnati, 1890; aged 49; chief of staff of the Good Samaritan Hospital, Kokomo; surgeon to the Union Traction Company of Indiana; city health officer of Kokomo; a specialist in surgery; while visiting at Winter Haven, Fla., was accidentally drowned, January 21.

William Frank Guilfoyle ⊕ **Capt., M. C., U. S. Army,** Philadelphia; University of Pennsylvania, Philadelphia, 1905; aged 36; who was on duty with the American Expeditionary Forces and assigned to the 111th Infantry, 28th Division, and was gassed several times; died in Base Hospital 31, Sept. 2, 1918, from exhaustion.

Guy Benjamin Taylor ⊕ **Asst Surg., Lieut. (j. g.), U. S. Navy,** Lexington, S. C.; Medical College of the State of South Carolina, Charleston, 1917; aged 25; who entered the Navy in October, 1917, and served in France until December last, when he was placed on duty at the U. S. Naval Hospital, Brooklyn; died in that institution, January 21, from pneumonia following influenza.

George Halsted Boylan, aged 74; surgeon in the French Army during the Franco-Prussian war; and decorated with the French Cross of Honor for distinguished service; a practitioner for fifty-four years, and for the last ten years a resident of Baltimore; died at his home, January 21, from pneumonia.

Bradford Ripley Alden Scott ⊕ **Lieut., M. C., U. S. Army,** San Antonio, Texas; University of Texas, Galveston, 1916; aged 30; formerly a member of the staff of the Southwestern Insane Asylum, San Antonio; on duty at Brooksfield, Texas; died at his home, November 12, from pneumonia following influenza.

Henry Courtney Evans ⊕ Youngstown, Ohio; Johns Hopkins University, Baltimore, 1900; aged 46; who served in the French Army, from January, 1916, to July, 1917, and was in charge of a base hospital at Ris-Organi, France, and was invalided home; died at his home, January 23, from pneumonia.

Theophilus Parvin Caplinger ⊕ **Major, M. C., U. S. Army,** Wallace, Ind.; Indiana Medical College, Indianapolis, 1907; aged 38; assistant medical chief at the base hospital, Camp Logan, Houston, Texas; died at that post, January 10, from peritonitis, four days after an operation for appendicitis.

Alfred N. Couture ⊕ Auburn, Calif.; Hahnemann Medical College of the Pacific, San Francisco, 1894; California Eclectic Medical College, Los Angeles, 1896; died in White Hospital, Sacramento, Calif., Dec. 26, 1918, from cholelithiasis, for the relief of which an operation had been performed.

John Woodley Wallace ⊕ Concord, N. C.; North Carolina Medical College, Charlotte, 1907; aged 35; one of the organizers of the Concord Hospital; a specialist in surgery; who was operated on in the Charlotte Sanitarium in December for appendicitis; died in that institution, January 9.

John Watson Sawyer, Dexter, Me.; Bowdoin Medical School, Brunswick and Portland, Me., 1894; aged 53; a member of the Maine Medical Association; for two terms a member [illegible] formerly medical examiner (coroner) for [illegible] . died at his home, January 22.

Albert Marinius Larson ⊕ **Lieut., M. C., U. S. Army,** Jasper, Minn.; University of Minnesota, Minneapolis, 1917; aged 29; on duty with the American Expeditionary Forces; died in American Red Cross Military Hospital No. 24, Mossley Hill, Liverpool, England, Oct. 13, 1918, from pneumonia.

Frank Blaisdell ⊕ Goffstown, N. H.; Dartmouth Medical School, Hanover, N. H., 1877; aged 66; formerly president of the New Hampshire Medical Society and of the New Hampshire Surgical Club; died at his home, January 16, from bronchopneumonia, following influenza.

Charles Arthur Robertson ⊕ **Lieut., M. C., U. S. Army,** Hopkinsville, Ky.; Vanderbilt University, Nashville, Tenn., 1917; aged 24; on duty with the American Expeditionary Forces in France; died, November 14, from lobar pneumonia following wounds received in action.

Albert George Bising ⊕ **Major, M. C., U. S. Army,** Weehawken, N. J.; College of Physicians and Surgeons in the City of New York, 1896; aged 48; on duty with the American Expeditionary Forces in France; died in Toul, France, Nov. 2, 1918, from pneumonia.

Frederic Weston Taylor ⊕ Cambridge, Mass.; Harvard Medical School, 1882; aged 62; visiting physician to Cambridge Hospital; a member of the Massachusetts Association of Boards of Health; died at his home, January 19, from heart disease.

Daniel P. Kennedy, Martinsville, Ind.; Eclectic Medical Institute, Cincinnati, 1870; aged 73; formerly mayor of Martinsville; secretary of the Board of Health; a veteran of the Civil War; died at his home, January 16, from cerebral hemorrhage.

Samuel McAlister Mauney ⊕ **Capt., M. C., U. S. Army,** Earl, Ark.; University of Tennessee, Nashville, 1914; aged 27; on duty with the American Expeditionary Forces in France; died at Nantes, France, November 1, from bronchial pneumonia.

James W. Graham, Washington, D. C.; George Washington University, Washington, 1877; a clerk in the patent office, Washington, since 1869; died at his home, January 13.

⊕ Indicates "Fellow" of the American Medical Association.

William John Davison ⊕ Lieut., M. C., U. S. Army, New Castle, Pa.; Medico-Chirurgical College of Philadelphia, 1905; aged 35; on duty at Debarkation Hospital No. 3, New York City; died in New York City recently from pneumonia.

Willis E. White, Mayville, N. D.; Miami Medical College, Cincinnati, 1886; aged 68; a member of the North Dakota State Medical Association; died in a hospital in Fargo, N. D., January 21, from cerebral hemorrhage.

Christian Fry, St. Paul; University of Louisville, Ky., 1874; aged 68; a well known hotel proprietor in St. Paul; formerly a druggist in Indianapolis; died at Miami, Fla., January 19, from cerebral hemorrhage.

Alfred Atwater MacKeen, Whitman, Mass.; Bellevue Hospital, Medical College, 1879; aged 64; a member of the Massachusetts Medical Society; was killed in Whitman, in an automobile accident, January 18.

Frank Abbott Bucklyn, Mystic, Conn.; Medical and Surgical College of the State of New Jersey, Jersey City, N. J., 1890; aged 51; died at his home, Dec. 27, 1918, from pneumonia following influenza.

Lawrence Carl Freeny ⊕ Pittsville, Md.; University of Maryland, Baltimore, 1900; aged 44; a specialist in surgery; died at his home, January 12, from peritonitis following an operation for appendicitis.

Edward Francis Phelan ⊕ Lieut., M. C., U. S. Army, North Brookfield, Mass.; University of Vermont, Burlington, 1909; aged 32; on duty with the British army, overseas; is reported to have died recently.

Claude Matthew Barton, Homestead, Pa.; University of Louisville, Ky., 1901; aged 41; at one time a member of the Medical Society of the State of Pennsylvania; died at his home, January 17.

Clifford Kirkpatrick ⊕ Adrian, Mich.; University of Michigan, Ann Arbor, 1881; aged 63; local surgeon of the Wabash Railroad; died at his home, Dec. 31, 1918, from peritonitis.

James Madison Earnst, Alliance, Ohio; Long Island College Hospital, Brooklyn, N. Y., 1875; aged 70; died in his rooms in Alliance, January 17, from cerebral hemorrhage.

Frank M. Stone, Shenandoah, Pa.; Jefferson Medical College, 1875; aged 60; was found dead in his room in the Mandous Hotel, Shenandoah, December 23.

Thomas Hugh Balfe, Hamilton, Ont.; Queens University, Kingston, Ont., 1892; aged 47; died at his home, November 5, from pneumonia following influenza.

Charles Henry Grimm, Sausalito, Calif.; Harvard Medical School, 1883; a ship surgeon for the Hind-Rolph Company, San Francisco; died at sea, January 3.

Horatio Havelock Hanson, Butte, Mont.; Columbus (Ohio) Medical College, 1881; aged 58; died at the home of his daughter in San Francisco, January 9.

Louis Vitkin, Victor, Idaho; Chicago College of Medicine and Surgery, 1913; aged 29; died at his home, November 9, from pneumonia following influenza.

Charles Dennis Kelley ⊕ Mount Vernon, N. Y.; University of Vermont, Burlington, 1894; aged 59; died at his home, January 17, from heart disease.

James B. Covey, Higginson, Ark.; Vanderbilt University, Nashville, Tenn., 1878; aged 68; died at his home, November 6, from pulmonary tuberculosis.

Almira Janette Wilson, Boston; Tuft's College Medical School, Boston, 1898; aged 58; died at her home, December 30, from arteriosclerosis.

Alexander Clayton Jacobs, Chicago; Marion-Sims Medical College, St. Louis, 1896; aged 44; died at his home, January 5, from influenza.

Henry P. Hargis, McCrory, Ark.; Memphis (Tenn.) Hospital Medical College, 1913; aged 56; died at his home, January 15, from tuberculosis.

Fred G. Ketchum, Springfield, Ill.; Hahnemann Medical College, Chicago, 1893; aged 54; died at his home, about January 9.

William Franklin Pollock ⊕ Pittsburgh; Western Reserve University, Cleveland, 1871; aged 78; died at his home, January 14.

Robert Winfried McCarter, Pittsburgh; University of Pittsburgh, 1896; aged 57; died at his home, January 10.

Adelbert D. Tilden, Riverside, Calif.; Eclectic Medical Institute, Cincinnati, 1876; died at his home, January 11.

Warren Adams Wright, Readfield, Me.; Harvard Medical School, 1862; aged 81; died at his home, January 6.

The Propaganda for Reform

In This Department Appear Reports of the Council on Pharmacy and Chemistry and of the Association Laboratory, Together with Other Matter Tending to Aid Intelligent Prescribing and to Oppose Medical Fraud on the Public and on the Profession

MISBRANDED NOSTRUMS

How the Bureau of Chemistry Is Protecting the Public Against Fraudulent or Misleading Advertised "Patent Medicines"

M. I. S. T. (Murray's Infallible System Tonic).—Sold by the M. I. S. T. Co., Toledo, Ohio. Analysis showed the product to contain mercury (probably in the form of calomel), emodin (probably from aloes), licorice, methyl salicylate, and compounds of iron, calcium and magnesium. Falsely and fraudulently advertised. Fine, $25 and costs.—[*Notice of Judgment No. 5890.*]

Great Nerve and Blood Tonic
M.I.S.T. No. 2
M.I.S.T. No. 2 HAS CURED

M. I. S. T. No. 2, Nerve Tonic.—Shipped by the M. I. S. T. Co., Toledo, Ohio. Analysis showed the sample to be a capsule consisting essentially of aloes, licorice, and other plant material, methyl salicylate, calomel and inorganic matter. Falsely and fraudulently adverised.[1] Fine, $25 and costs. —[*Notice of Judgment No. 5898.*]

Imperial Remedy.—Shipped by the Imperial Medicine Co., Houston, Texas. Analysis showed the product to consist essentially of a water-alcohol solution of glycerin, chloral hydrate, carbolic acid, benzoic and salicylic acids. Falsely and fraudulently advertised. Fine, $100.—[*Notice of Judgment No. 5893.*]

"Japanese Wild Cherry Cough Syrup," and "Japanese Herb Laxative Compound."—Shipped by Torata Tanaka, who traded as the Japanese Remedy Co., St. Louis. Analysis of the "Cough Syrup" showed it to consist essentially of a water-alcohol solution of plant material and menthol, while that of the "Laxative Compound" was found to be essentially a dilute water-alcohol solution of plant material bearing emodin. Both were falsely and fraudulently advertised. Fine, $75 and costs.—[*Notice of Judgment No. 5836.*]

Dr. E. E. Burnside's Purifico.—Shipped by Charles W. and Pearl B. Diffin, copartners, who traded as the Purifico Co., Buffalo. Samples of "Purifico Nos. 1, 2 and 3" were analyzed. "No. 1" was found to contain 10 per cent. of alcohol, with sugar, small amounts of glycerin, potassium iodid, cinchona alkaloids, piperin and emodin (probably senna). "No. 2" was found to contain 9 per cent. of alcohol, sugars, small amounts of glycerin, potassium iodid, cinchona alkaloids and piperin. "No. 3" was found to contain 14 per cent. of alcohol, sugars, valerian, piperin and tannic acid. All three products were falsely and fraudulently advertised. Fine, $25.—[*Notice of Judgment No. 5896.*]

Emerald Oil.—Shipped by the Moone Chemical Co., Rochester, N. Y. Analysis showed the sample to be essentially a solution of camphor, carbolic acid and oil of sassafras. Falsely and fraudulently advertised. Fine, $25.—[*Notice of Judgment No. 5897.*]

Bristol's Sarsaparilla.—Shipped by Mary Augusta, Edward, and Edward Charles Mears Kemp, who did business as Lanman and Kemp, New York City. Analysis showed the product to consist essentially of a water-alcohol solution of potassium iodid, sugar and plant extractives, with indications of sarsaparilla and arbutin. Falsely and fraudulently advertised. Fine, $50.—[*Notice of Judgment No. 5822.*]

---

[1] This preparation was analyzed by the Chemical Laboratory of the American Medical Association, and the results published in the Propaganda department of The Journal, July 31, 1915. The matter is reprinted in the pamphlet, "Miscellaneous Nostrums," published by the American Medical Association, price 15 cents.

Dr. Belding's Six Prairie Herbs.—Shipped by the Dr. Belding Medicine Co., Minneapolis. Government chemists reported that the odor and taste suggested that of highly diluted and sweetened whisky, with a very small amount of some indifferent herb or herbs. Falsely and fraudulently advertised. Fine, $10.—[*Notice of Judgment No. 5895.*]

Dr. Carter's K. & B. Tea.—Shipped by S. C. Wells & Co., Le Roy, N. Y. Analysis showed the product to consist of senna, liverwort, and wintergreen leaves and juniper berries, with buchu and boneset leaves and possibly uva ursi (bearberry) leaves. Falsely and fraudulently advertised. Fine, $25.—[*Notice of Judgment No. 5904.*]

"Brazilian Balm" and "Renal Tea."—Shipped by Benjamin F. Jackson, who traded as B. F. Jackson & Co., Arcade, N. Y. Analysis showed the "Brazilian Balm" to contain essentially water, alcohol, glycerin, sugar, aconitin and berberin, flavored with methyl salicylate. The "Renal Tea" was found to consist of plant material. Both were falsely and fraudulently advertised. Fine, $25.—[*Notice of Judgment No. 5929.*]

Las-I-Go for Superb Manhood.—Shipped by Wm. J. Bailey and Wm. Veeler, trading as the Lakeside Medicine Co., Chicago. Analysis showed this preparation to be a pill that *was essentially a slight variation of the ordinary Blaud's pill* with strychnin. Falsely and fraudulently advertised. Fine, $200 and costs.—[*Notice of Judgment No. 5932.*]

Blood Tabs.—Shipped by the Reese Chemical Co., Cleveland. Analysis showed the preparation to consist of brownish, sugar-coated *pills, containing carbonate of lime, the* interior being a pasty mass containing sulphates and carbonates of iron and potassium, also iodid of potassium, glycerin, and reducing sugar. Falsely and fraudulently advertised. Fine, $25 and costs.—[*Notice of Judgment No. 5596.*]

Dr. Mile's Restorative Nervine.—Shipped by Charles Franklin Miles, Andrew H. Beardsley and Albert R. Beardsley, trading as the Dr. Miles Medical Co., Elkhart, Ind. Analysis showed the product to consist essentially of a watery solution of sugar, benzoic acid, arsenic, and bromids and chlorids of ammonium, calcium, potassium and sodium, colored and flavored. Falsely and fraudulently advertised.[1] C. F. Miles fined $200 and costs and A. R. and A. H. Beardsley each fined $100 and costs.—[*Notice of Judgment No. 5891.*]

Kilmer's Swamp Root.—Consigned by Dr. Kilmer & Co., Binghamton, N. Y., to Porto Rico. Falsely and fraudulently advertised (in labels and circulars printed in German, Spanish, Italian, Portuguese and French) as a treatment for Bright's disease, acute nephritis, cancer of the liver, acute and chronic gonorrhea, etc. Court ordered entry of a decree of condemnation and forfeiture, and the product was delivered to Dr. Kilmer & Co., after the concern had paid the costs of the proceedings, and given a bond for $150.—[*Notice of Judgment No. 5946.*]

Homenta.—Shipped by the New York Drug Concern (Laurence E. Cash), New York City. Analysis showed the product to be a dark-colored liquid with a small amount of oil floating on the top or emulsified, and consisting essentially of menthol, thymol, ammonia, sugar (over 61 per cent.), water and alcohol (4.6 per cent.). Falsely and fraudulently advertised. Fine, $25.—[*Notice of Judgment No. 5702.*]

Hinkley's Bone Liniment.—Shipped by the Hinkley Bone Liniment Co., Saginaw, Mich. Analysis showed the sample *to be a water-alcohol solution of volatile camphoraceous oil,* with indications of red pepper. Falsely and fraudulently advertised. Fine, $50.—[*Notice of Judgment No. 5945.*]

Kopp's Baby's Friend, Kopp's, and Kopp's Kidney Pills.—Shipped by the Kopp's Baby's Friend Co., York, Pa. Analyses *showed* the "Baby's Friend" and "Kopp's" to be a syrup containing alcohol, morphin, and aromatic substances.[2] The "Kidney Pills" were found to contain chiefly methylene blue, juniper, and unidentified matter. All three were falsely and fraudu*lently advertised.* Fine, $25 and costs.—[*Notice of Judgment No. 5646.*]

Reuter's Syrup.—Shipped by Barclay & Co., New York City. Analysis showed the product to be essentially a water-alcohol *solution of sugar, aromatics, and a cathartic* drug. Falsely and fraudulently advertised. Fine, $100.—[*Notice of Judgment No. 5647.*]

Garfield Tea.—Shipped by the Garfield Tea Co., Brooklyn. Analysis showed the preparation to consist essentially of senna leaf and triticum (cough-grass), a small amount of valva (mallow) flowers and fruits, and mint stems; also traces of unidentified plant tissue, and a small amount of a substance resembling manna. Falsely and fraudulently advertised. Fine, $25.—[*Notice of Judgment No. 5670.*]

Di-Col-Q.—Shipped by the New York Drug Concern (Laurence E. Cash), New York City. Analysis showed the *product to consist essentially of pine oil, chloroform,* mineral oil, and a green dye. Falsely and fraudulently advertised. Fine, $25.—[*Notice of Judgment No. 5703.*]

Sloan's Liniment.—Sold by Dr. Earl S. Sloan (Inc.), Philadelphia. Analysis showed the preparation to be a reddish *liquid containing essentially* turpentine, a light oil having the characteristic of kerosene or coal oil, oil of sassafras, oleoresin of capsicum with indications of pine oil. Falsely and fraudulently advertised. Fine, $50.—[*Notice of Judgment No. 5659.*]

Bannerman's Intravenous Solution.—Shipped by William Bannerman & Co., Chicago. Adulterated in that its strength and purity was below that claimed; misbranded because it was falsely and misleadingly labeled.[3] Fine, $25 and costs.—[*Notice of Judgment No. 5664.*]

Cummings Blood Remedy.—Shipped by Edwin D. Richardson, who traded as F. P. Cummings Co., Roanoke, Va. Analysis showed the stuff to contain over 20 per cent. of alcohol with plant *extractives, sarsaparilla, potassium* iodid, and sugar. Falsely and fraudulently advertised. Fine, $50.—[*Notice of Judgment No. 5684.*]

Giles' Germicide.—Shipped by the Giles Remedy Co., Chicago. Analysis showed the preparation to be an oily mixture containing chiefly linseed oil, ether and camphor. Falsely and fraudulently advertised. Fine, $50.—[*Notice of Judgment No. 5639.*]

---

[1] This fraudulently advertised nostrum was analyzed by the A. M. A. Chemical Laboratory in 1916 and the report published in the Propaganda department of The Journal, Sept. 9, 1916. The matter is reprinted in the pamphlet "Epilepsy Cures," price 10 cents.

[2] The "baby killer," "Kopp's Baby's Friend," was analyzed by the American Medical Association in 1905. A list of deaths and poisonings from this product is given in "Nostrums and Quackery," 2d edition.

[3] This preparation was the subject of a report of the Council on Pharmacy and Chemistry which appeared in The Journal A. M. A. Jan. 2, 1915, and is reprinted in the "Propaganda for Reform" ([illegible] Edition).

MISLEADING CERTIFICATES FOR CLINICAL THERMOMETERS

o the Editor:—It has been brought to the attention of Bureau of Standards that clinical thermometers are gularly being sold with certificates of accuracy issued by nufacturers and dealers which either direct statement or indirectly by ilful wording lead the purchaser to lieve that the thermometers have en tested or certified by the United ates Government.

An examination of the accompany-g reproductions of certificates indi-tes very clearly the reason for the isunderstanding. Note the similar-y between the older form of govern-ent certificate shown in Figure 1 d the three forms of manufacturer's rtificates shown in Figure 2.

The words "National Bureau of tandards" are very prominent on ese manufacturer's certificates, and e name of the maker is omitted en-rely. In fact, nine out of ten per-ons reading any one of these certifi-ates would fail to note that the omplete statement is to the effect at the clinical thermometer has been ompared with *our standards* corrected by National Bureau f Standards. "Our" refers to the standards of the manu-cturers of the instruments; and while the validity of the atement is difficult to prove or disprove, since certified inical standards may have been furnished the manufac-rers, the reliability of the thermometer depends solely on e manufacturer, who may or may not have carefully tested e instrument. That many manufacturers do not make such reful tests is indicated by the fact that while practically l of such certificates show correct readings at all points, tual tests of the instruments show that only a very small rcentage read correctly at all points on the scale.

NOTE: When the corections are + it must be added to the observed reading, and when − subtracted.

The corrections in the foregoing table are applicable to that Thermometer only which is described by name and number above.

CERTIFICATE
OF
EXAMINATION

This Certifies that Clinical Thermometer No. 57314 has been compared with our Standards *Corrected by National Bureau of* Standards and the following readings observed:

Points of Observation on Standard.	Correction.
96°	− 0
100°	− 0
104°	− 0
108°	− 0

NOTE—When the correction is preceded by a + sign it must be added to the Thermometer reading when − subtracted

The instrument described above has a fixed zero point, having been Standardized before the scale markings were made and will not increase its readings.

THIS CERTIFIES
That Clinical Thermometer
No. 1168
has been compared with Standard Thermometer

Verified by the U. S. Bureau of Standards, and the following show the correct reading of the scale.

Thermometer Reading	Corrections
95°	−0 0
100°	−0 0
105°	−0 0
110°	−0 0

NOTE—When the correction is + it must be added to the observed reading and when − subtracted

The corrections in the foregoing table are applicable to that Thermometer only which is described by name and number above

☞ Please note that the Thermometer is graduated in Fifths and the corrections in Tenths.

Fig. 2.—Types of misleading clinical thermometer certificates issued by manufacturers and dealers.

The Bureau of Standards has not taken the position that nufacturers should not issue certificates for thermometers, ovided the certificates are the result of careful testing, are t deceptively worded, and bear the manufacturer's name.

There are reliable manufacturers turning out high grade instruments who issue their own certificates over their own names. These manufacturers are being done an injustice by their competitors, who, without even testing a thermometer, boldly state that it has no errors and is sold in accordance with the requirements of the United States Government.

Only recently the bureau was requested to replace or refund the money paid for a clinical thermometer which the purchaser had inferred from the certificate (one of those shown) had been tested and guaranteed by the government.

The certificate dated Sept. 22, 1917, shown in Figure 1, is *the form now* issued by the National Bureau of Standards unless the other form is specifically requested. The distinctive form should be noted. The seal of the Bureau of Standards appears over the face of the certificate. Up to this time no counterfeits of this new form have been brought to the bureau's attention.

The Bureau of Standards has issued a publication (Circular No. 5) on the testing of clinical thermometers, which will be sent to any one sufficiently interested. The publication answers more in detail some of the questions touched on in this letter and contains considerable additional information in regard to clinical thermometers.

The bureau hopes that you will consider this matter of sufficient interest to your readers to warrant publication of this letter, or otherwise giving publicity to this question in THE JOURNAL.

S. W. STRATTON, Washington, D. C.
Director, Bureau of Standards, Department of Commerce.

ADVANTAGE OF PRINTING ON ALTERNATE PAGES

To the Editor:—The busy physician nowadays resorts a great deal to the collection of data under specific heads for future reference, and for this reason is prone to take clippings from medical journals and file them under titles of subjects in matters wherein he is particularly interested. Only in those cases in which the physician has at his disposal paid clerical assistants for the purpose of this classification could he, in the present situation, have made a card index to articles in medical journals. Speaking from my personal experience, I find it much more satisfactory to cut out the article and file it in an envelop under the title of the subject. This being the case, it is somewhat troublesome in cutting out a valuable article to find on the opposite side of the page all or part of another equally valuable article on a different topic, which necessitates having a typewritten copy of the page made to go with the second article.

Book Notices

Surgical Treatment: A Practical Treatise on the Therapy of Surgical Diseases for the Use of Practitioners and Students of Surgery. By James Peter Warbasse, M.D., Surgeon to the Wyckoff Heights Hospital. In 3 volumes. Cloth. Price, $30 per set. Philadelphia: W. B. Saunders Company, 1918.

A three volume work such as this by a single author is a large undertaking; but Dr. Warbasse seems to have succeeded in giving us a rational and comprehensive presentation of surgical treatment. If there is any criticism to be made of his work, it is that there is so much included that the author's individuality and opinion on the various subjects considered is in many cases not easily ascertained. The work has avoided a large amount of duplication which usually occurs in works of composite authorship. Volume I presents the theory and principles of surgery, the treatment of lesions of the blood and lymphatic vessels, fractures and dislocations, tumors, and diseases of the bones, joints, muscles, tendons, nerves, and of the skin and its appendages. Volume II includes the surgery of the head, spine, neck, thorax, breast and abdomen. As stated in the preface, the work contains few references to the discoverers of methods and of instruments, because a continued search of the literature has revealed the fallacy of proper name nomenclature in surgery; most instruments and procedures bearing proper names were used before the time of the individual whose name they bear. This is a matter requiring good judgment, since we are governed in these matters largely by general usage. For example, the Murphy drip, although not original with Dr. Murphy but popularized by him, is better described by the term "drip method proctoclysis." On the other hand, incision of the pylorus in pylorospasm has come to be known as the Rammstedt operation and is so described in indexes. Dr. Warbasse does not call this the Rammstedt operation, although he describes the method. Incidentally he credits it with some beneficial results without, however, stating any of the possible dangers.

It is a question whether it is advisable to state (page 299) that "self healing" of syphilis occurs, and that "an otherwise healthy person who leads a hygienic life may recover from syphilis without treatment," since such cases are at best of extremely rare occurrence. In his description of tests for lysis and agglutination preliminary to blood transfusion, the author does not describe the methods which recently have been given the greater preference by military surgeons. He agrees with most surgeons that the most simple, useful and effective method of transfusion is the citrate method.

The books are well printed and excellently illustrated with numerous good halftones and a number of colored illustrations. Incidentally there are a few illustrations that might well be omitted, since the objects illustrated are common. Figure 5 illustrates a bedpan; Figure 6, a douchepan; Figure 164 is just a plain, common, ordinary icebag. It is certainly desirable to use illustrations freely in medical, as well as in other literature; but this, like anything else, may easily be overdone. However, these are minor criticisms of what is on the whole a well prepared, thorough and exceedingly practical work.

Oxford Loose-Leaf Surgery. By Various Authors. Edited by F. F. Burghard, M.S., F.R.C.S., Colonel, A. M. S., Lecturer on Surgery and Surgeon to King's College Hospital, London, and Allen B. Kanavel, A.B., M.D., F.A.C.S., Lieut. Col. U. S. A., Associate Professor of Surgery Northwestern University Medical School, Chicago. In five volumes. Volume One. Cloth. Price, $32.50 per set. Pp. 971, with 354 illustrations. New York: Oxford University Press, 1918.

The first volume of this system of surgery deals with general surgery, among the contributors being Percy Sargent, D'Arcy Power, F. F. Burghard, W. Sampson Handley, Robert Jones, and among American surgeons; Dunlap Pearce Penhallow, N. M. Percy and Richard Lewisohn. This volume concerns such subjects as the principles and technic of aseptic surgery, gunshot wounds, the Carrel-Dakin method, antiseptics, anesthetics, amputations, blood transfusion, ligations, surgery of the lymphatics, and injuries of the joints. In the preface the editors state that originality and individuality will be sought rather than a colorless enumeration of operative procedures, and that categorical enumeration of operations of merely historical interest will be avoided. Nevertheless, much of the material in this volume is of the same stereotyped character as occurs in most textbooks on surgery. This, of course, refers particularly to the discussion of the elementary factors and the ordinary ligations and amputations.

Chapter V, on the subject of syphilis, has in it very little of special surgical interest, and might just as well appear in any book on any phase of medicine, being simply an ordinary statement on the subject. This section is not complete, and far better statements on syphilis appear in many textbooks. This applies particularly to that portion of the article referring to tabes and to the section on the luetin test. It would appear to be time already for a new loose leaf section on surgical syphilis. Chapter I of the second section, concerning infiltration and anesthesia, is practically a full abstract of Barker's papers published in the *British Medical Journal* in 1904 and 1907, together with the present experiences of the writer, J. W. H. Houghton. Chapter IV in this section, by P. L. Guiseppi, on scopolamin-morphin anesthesia in obstetrics, asserts that such anesthesia is practically safe with ordinary precautions, and that the only danger is that of stillbirth. This chapter would also appear to call for a new loose leaf section, since it is at least a few years out of date. Chapter VII of this section is entitled "Diet in Surgery," certainly a large title for three pages of material consisting of a few words on rectal feeding and the Lenhartz diet, and from twenty-five to thirty lines on diabetic diet before operation. Most of the remaining sections of the book are practical and well illustrated, following, however, the usual lines for books on general surgery. An exception is the eighth section on injuries of the joints. This is prepared by Sir Robert Jones of Liverpool, and is characteristically terse and authoritative, probably the most valuable section of the first volume.

This textbook is an innovation in medical book publishing, although the loose leaf idea has already been applied to an encyclopedia of general nature. Such success as it achieves will probably depend on the character of the supplements to be issued, their frequency, and the proper use of such supplements by libraries and subscribers. On the whole, the book is well printed and illustrated and marks the beginning of what must be regarded as an interesting venture in medical publication.

Gun-Shot Fractures of the Extremities. By Joseph A. Blake, *Lieutenant-Colonel, Medical Corps, U. S. A.* Paper. *Price, 4 francs.* Pp. 136, with 40 illustrations. Paris: Masson & Cie, 1918.

This is one of the most instructive monographs summarizing the treatment of gunshot wounds. Dr. Blake's experience peculiarly fits him to write such a book. His wide experience as a general surgeon before the war and his opportunity of studying this subject during the war, coupled with his ability to weigh all the evidence and arrive at a judicial opinion, give his conclusions great weight. The monograph is divided into two sections: The first one treats of the general topics of the mechanism and varieties of gunshot fractures, the repair of fractures, the transport and operative treatment of fractures in general, and mechanical treatment. The second section, on special fractures, takes up the subject of diaphysial fractures and fractures and wounds of joints. The book is the result of an intensive study covering four years and a large amount of material, and of the work Dr. Blake did in the American Ambulance Hospital and later with the American Expeditionary Forces. He presents rather fully the great value of the proper handling of fractures of the extremities for transport, and emphasizes the importance for this purpose of the Thomas traction splints for both the upper and the lower extremities. He describes fully the greatest lesson that has been taught to surgeons by this war, the possibility of sterilizing a gunshot wound by clean dissection and by removing all of the injured tissue and foreign bodies, making it possible to secure in this way primary union in from 80 to 90 per cent. of the cases if this is properly done in the period of contamination in the first six or eight hours after receipt of the injury. He points out the necessity of saving all attached bony fragments, and the futility of bone plating and the leaving of foreign material in the wound.

The discussion of fractures of the femur is accompanied by excellent illustrations of the modified Thomas traction leg splint and of the Hodgen leg splint, and of suspension frame for fractures that was devised and perfected at the American Ambulance Hospital, planned for the purpose of suspension and for traction apparatus on the limbs, and so arranged that direct extension and lateral traction can be employed at the same time.

The chapter on fractures and wounds of the joints is of special value. Blake states that the experience during the war has unequivocally proved that the ideas formerly prevalent concerning the extreme susceptibility of the synovial membrane were erroneous, and describes how by good technic in the removal of foreign bodies and injured tissues these joint wounds can be mechanically sterilized and closed with an excellent prospect of securing primary union and good functional results. In civil practice we of course do not have the enormous number of gross traumatisms of the extremities that we encounter in time of war; but essentially the same sort of injuries of bones and joints occur in railroad accidents and in industrial injuries, in automobile accidents, etc., and these require the application of the same general principles that have been emphasized by the experience of the war.

It would be of advantage to general surgeons who have to assume the responsibility of handling these serious injuries to read Blake's monograph and give their patients the benefit of the great advances that have been made in handling these injuries through the experience gained by surgeons in this war.

Tumours, Innocent and Malignant: Their Clinical Characters and Appropriate Treatment. By Sir John Bland-Sutton, LL.D., F.R.C.S., Surgeon to, and Chairman of the Cancer Investigation Committee of, the Middlesex Hospital. Sixth edition. Cloth. Price, $7. Pp. 790, with 383 illustrations. New York: Paul B. Hoeber, 1918.

In our note on the fourth edition of this work, it was pointed out that it was not a book that would give satisfaction to a pathologist, since the discussions of the histology of tumors are not satisfactory, and the illustrations are line drawings and woodcuts of only average workmanship. The sixth edition has been somewhat extended by the addition of new material, but no improvement has been made in these two primary weaknesses. Some eighty new illustrations have been added, but these are of the same class as the earlier illustrations. We would emphasize what was said in our previous review, viz., that the lists of literature appended to each chapter are of little value since the references are incomplete and confined almost wholly to a few British publications with only here and there a reference to literature of other countries. The book is interesting primarily for its general consideration of the various types of tumors, particularly with reference to comparative pathology. As the author says, without the aid of comparative pathology, attempts to catch the deeper meaning of many tumors are as difficult as endeavors to decipher a palimpsest in which the first characters, written in an unknown tongue, have been imperfectly removed from the parchment, and are allowed to mingle with the second inscription.

Mental Diseases: A Handbook Dealing with Diagnosis and Classification. By Walter Vose Gulick, M.D., Assistant Superintendent Western State Hospital. Cloth. Price, $2. Pp. 142, with illustrations. St. Louis: C. V. Mosby Company, 1918.

The subtitle states that this book deals with diagnosis and classification. It does, to the extent of about eighty-seven pages of text. The introduction informs us that "this little book" is a response to a need for "concise, digested information." But brevity is not a synonym for conciseness. The contribution is brief but the style is not concise. Nor is the information digested. This "handbook" is about the size of a quiz compend, without the latter's condensed and systematic information. Those desiring a sketchy smattering of not very accurate knowledge of mental disorders may perhaps be satisfied with this work. Thirty-five photographs of insane patients adorn the work but fail to illuminate the subject.

Social Medicine, Medical Economics and Miscellany

EPIDEMIC INFLUENZA IN THE MEDICAL AND SURGICAL HISTORY OF THE CIVIL WAR

LOY MCAFEE, M.D.
Contract Surgeon, U. S. Army; Secretary, Board of Publications, and Assistant, Division of Medical and Surgical History, Surgeon-General's Office
Washington, D. C.

As part of the work in the Office of the Surgeon-General, preliminary to collecting data for the forthcoming medical and surgical history of American participation in the European war, a digest was made of the preliminary volume ("Circular No. 6") of the "Medical and Surgical History of the War of the Rebellion," and of the six large volumes (three medical and three surgical) that constitute the history proper. The object was to make this material available in simple outline to those persons delegated by the Surgeon-General to formulate the forthcoming history. This would facilitate comparison and quick reference regarding the general plan and scope of the earlier work, the epidemics encountered, and the various other questions that might arise in this connection.

Among other aspects of this research was the one involving a study of the epidemic diseases encountered during the Civil War as compared with those that have characterized the present conflict. Quite naturally, in view of the recent pandemic, influenza received special attention in this regard.

HISTORY OF INFLUENZA

In his "History of Epidemics in Britain" (two volumes. 1894), Creighton gives the history of influenza, a disease which, under various names, can be identified clearly enough in certain instances, even in the earliest times.

As early as the year 1554, we are told, the Venetian ambassador in London called the sweating sickness of 1551 an influenza. This is the Italian form of the Latin "influxio," meaning catarrh. Creighton thinks the term was the outgrowth of the old humoral pathology.

In 1712 the "new ague" appeared, to which the French applied the name "la grippe," the Germans "Galanterie-Krankheit" and "Mode-Krankheit," all meaning "the disease *à la mode*," the first figuratively.

In 1743 the Italian word "influenza" first appeared in England, when the rumor of a great epidemic at Rome and elsewhere in Italy, called by this name, reached England a month or two before the disease itself.

This epidemic was of short duration, and with its passing the Italian name, likewise, was generally forgotten until 1762, when some one suggested that the disease then epidemic was "the disease called influenza" twenty years before. Another epidemic, in 1782, served to bring the name into general use. After the great epidemics of 1833 and 1847, more than a generation passed with little disturbance from this source. Then came the great pandemic which began in Russia in 1889 and spread from country to country, with recrudescences, lasting until 1894.

In our own country it seems that influenza has appeared in sporadic, epidemic and pandemic form. The first epidemic described, which swept the country and extended to the West Indies, was that of 1647, recorded by Noah Webster. In 1655 there was a second. Others, in 1789 and 1807, were described by Benjamin Rush and Daniel Drake, respectively.

In this country, as elsewhere, the disease has appeared under different names, and, as in England, the term "influenza" became both "popular and vague."

It is not surprising, therefore, to find, in the "Medical and Surgical History of the War of the Rebellion," a confusion of the terms "acute catarrh," "acute bronchitis," and "epidemic influenza," as applied to affections presenting the general symptomatology, with the same variations in detail, as have been noted in the present pandemic.

RELATIONSHIP BETWEEN INFLUENZA AND EPIDEMIC CEREBROSPINAL MENINGITIS

It is interesting, in this connection, to learn that observers during the Civil War noted an apparent relationship between what was then called "spotted fever" (epidemic cerebrospinal meningitis) and epidemic influenza.

The American Medical Association appointed a "committee on 'spotted fever, so-called,'" an epidemic of which was then (1863) in progress in Philadelphia and vicinity. The report of this committee appeared in the Transactions of the Association in 1866.

We find (p. 337) that "when the attention of the profession in Philadelphia was called to the existence of spotted fever, there was prevailing in that city a severe and widespread epidemic of *influenza*, or epidemic catarrhal fever. . . . Several medical men in active practice were at once struck with the resemblance of many of the symptoms of the two diseases, and were led to inquire if influenza might not be but a milder manifestation of that epidemic influence which in its intensity produced spotted fever. Nor, it will seem, were their symptoms very dissimilar save in degree. Suddenness of attack, intense pain in the head and back, great nervous depression associated with marked hyperesthesia, great precordial distress, nausea and vomiting were common to the two diseases. So, too, were certain incidental phenomena, such as the occurrence of irregular forms of cutaneous eruptions, roseola and urticaria, occasional glandular swellings and rheumatoid affections of the joints." Some acknowledged and some ridiculed the idea of the resemblance. Some regarded influenza and spotted fever as "two diseases as in no way differing but in degree and seat of their urgent symptoms." One contemporary writer called spotted fever "malignant influenza." This writer, Dr. North, proposed the following classification: When the disease exists with simple inflammation of the air passages, i. e., ordinary influenza, "febris catarrhalis"; when with pleurisy or pneumonia, "febris catarrhalis synocha major"; when in severest form, "febris catarrhalis maxima, or spotted fever."

Canstatt, in "Die Specielle Pathologie und Therapie," considered spotted fever as "epidemic catarrh complicated with putrid or adynamic fever."

It will be interesting in this connection to note the results of studies, now being made, of the brains and spinal cords of patients who have succumbed to influenzal pneumonia during the recent epidemic.

INFLUENZA DURING THE CIVIL WAR

In the third medical volume of the "Medical and Surgical History of the War of the Rebellion" (p. 725 *et seq.*), the following statements appear with reference to epidemic catarrh:

"During the fourteen months, May, 1861, to June, 1862, inclusive, 85,677 cases of 'catarrh,' six of which terminated fatally, were reported among the white troops. No particulars of these cases have been recorded." The term "acute bronchitis" was substituted for "catarrh" on the monthly reports of sick and wounded. Among the white troops 134,397 cases were reported, and among the colored troops, 9,869. Throughout the several years covered by the statistics, the average annual rate was 61.4 per thousand strength among the white and 53.8 among colored troops. The quartering of the troops in unaccustomed circumstances as to climate and general surroundings, the crowding, the fatigue, etc., were thought to exert an influence in the causation of the epidemics. "Its raw material, under the exposures of the bivouac, became affected with catarrh associated with great disturbance of the system and unusual prostration, which was due rather to the unaccustomed fatigues and privations undergone by the men than to any epidemic influence.".

The surgeon of the Twentieth Indiana, located in Maryland, reported that soon after camping at Fortress Monroe (September, 1861), an epidemic of influenza appeared in his regiment. The cough was violent and persistent, but the constitutional disturbance, according to the surgeon, was slight. This epidemic was preceded by another that affected a neighboring camp. In the latter epidemic, which was described by the surgeon in charge in the *Medical and Surgical Reporter*, Philadelphia (**7**:189, 1861-1862), the respiratory passages, as a rule, were not severely affected, although in some cases uneasiness in the chest, and the expectoration of blood, were noted. The disease was marked by a severe and almost invariable pain in the frontal region, which sometimes extended over the whole head, by pains in the loins, aching in the lower extremities, and pain in the neck and arms. Intestinal disorder also was prominent, evinced by severe diarrhea, with frequent watery, bloody and mixed stools, tenesmus and tenderness of the abdomen. There was great debility, but there was not great febrile disturbance. The epidemic lasted more than two weeks.

Another surgeon, from a neighboring camp, reported an epidemic at about the same time, nearly every man in the regiment being more or less affected by it. In this instance, unlike the one just mentioned, the disease was characterized by severe aching, throbbing pains in the head, back and limbs, bronchial inflammation and hepatic disorder. In all cases, in its severest phases, it was followed by unusual physical debility and tedious convalescence.

"Acute bronchitis," the term later applied to "epidemic catarrh," was held responsible for 168,715 cases of sickness, among the white troops, with 650 fatalities—an average annual rate of 76.8 cases and 0.27 deaths per thousand. Among the colored troops there were 22,648 cases, and 255 deaths, giving an average annual rate of 123.5 cases and 1.33 deaths, and a mortality rate of 1.12 per cent. of the cases.

The association of pneumonia with influenza, in these epidemics, though not unknown, was evidently not so frequent an occurrence as to render the mortality very striking.

We find (p. 783) that the records contain 135 cases of lobular pneumonia secondary to acute bronchitis or other morbid processes in the lungs in men whose vitality was reduced by previous attacks of disease.

The Feebleminded and Prostitution

In the *Social Hygiene Monthly* for October, Katherine Ostrander discusses the menace of the feebleminded prostitute. Figures are given of the results of the working of the laws and regulations in Michigan. Six hundred and seventy-five women patients were admitted for venereal treatment throughout the state. Of these, 391 were discharged as being no longer in an infectious state, leaving 284 women under treatment. Of the 391 women, 385 were acknowledged or unacknowledged prostitutes. Of the discharged women, twenty were recommended for care in the Michigan Home and Training School at Lapeer, but could not be taken because of lack of room. Sixty of the women were found to be retarded mentally, but not to a degree making institutional care necessary. They are high grade morons, physically attractive, and appear normal, but are incapable of deciding for themselves right and wrong and are a constant menace. Of the 391 discharged, seven, or 2 per cent., were returned to the hospitals reinfected. All but one of these were feebleminded. The figures given of the disposition of the discharged women shows the great difficulty of making any permanent progress in the spread of venereal diseases through the handling of these women without permanent segregation and custodial care. In psychopathic clinics established in Detroit and some other cities of the state, out of 247 women examined, forty-five were pronounced totally feebleminded and unable to adapt themselves to society, and though twenty of them were diagnosed as imbeciles, they could not be institutionalized through lack of room in the institutions of the state, and will return again to their old haunts. Feebleminded and psychopaths not of a degree to demand institutional care amounted to 35 per cent. of the whole, and 35 per cent. of these, it is said, have little hope of complete reformation without constant personal supervision. Ostrander says that the most difficult of all social problems is the high grade feebleminded person, who looks normal, but is restless, lacks power of decision, has no will, no tenacity or power of concentration and will always be carried by any will stronger than her own.

Medicolegal

Expert Testimony as to Value of Services

(Terrill v. Fotheringham (Wash.), 173 Pac. R. 748)

The Supreme Court of Washington, in affirming the judgment rendered in favor of the plaintiff, a physician, does not state the amount he sued for, nor the amount for which the judgment was rendered, but says that he sued the executor of the estate of a former patient on account of services rendered to such patient in his last illness, which account consisted, not of unit prices, but an aggregate sum, and, not being satisfied with the amount the trial court allowed him, he appealed. The patient was a resident of Seattle who went to San Francisco, where he received the professional services of the plaintiff. The trial was without a jury and there was no dispute as to the facts or findings, except as to the value of the services.

The plaintiff applied for a commission to take the depositions of five physicians in San Francisco as to the value of the services. The court refused except for three, other than the plaintiff, and this was assigned as error. It is apparent that this was a matter within the discretion of the trial court with reference to something that was neither exact nor scientific. It possessed no element of knowledge, but consisted of pure opinion. Such expert evidence, even if uncontradicted, is not conclusive, but merely advisory—only a guide.

In this connection, it may be noticed that, as against these three, there were two witnesses for the defendant. Two physicians of Seattle testified for the defendant, and this was charged as error, on the theory that a physician residing elsewhere than in San Francisco was not qualified to testify, since the services were rendered there. Whatever may be the general rule in this regard was not controlling here, for an understanding of the nature and kind of disease, known of by all physicians, in respect to the care and attention it exacts from the attending physician, could with ease be, and was, testified to by these two physicians, thus being of help to the court in weighing and appropriating the advisory testimony of all as to the value of the services, the ultimate concern of the court. If, in testifying, they, who must have some general idea of such values, do express themselves as to the amount, how shall it be well claimed as error? For at most it would in this respect be only immaterial, a quality which in cases tried to the court will find no reflection in the judgment reached. There was no mistake of law by the court in the trial.

Hospital Not Liable for Medical Superintendent's Breach of Contract

(Davin v. Kansas Medical, Missionary & Benevolent Association (Kan.), 172 Pac. R. 1002)

The Supreme Court of Kansas holds that a charitable hospital corporation is not liable in damages for the failure of its medical superintendent to comply with a contract made by him for the care of a patient being treated in the hospital. The court says that the defendant was a charitable corporation organized under the laws of Kansas for purely philanthropic purposes, and conducted a hospital, or sanatorium. The plaintiff was afflicted with melancholia and was, by her husband, taken to the defendant's hospital. He stayed with her a couple of days, when he was advised by the defendant's medical superintendent to go home and stay away from the plaintiff. He agreed to do so on condition that a nurse be placed in charge of the plaintiff at all times, and that she be not left alone. To this the medical superintendent assented. A special nurse was placed in charge of the plaintiff, but the nurse did not remain in the room with the plaintiff at all times. The nurse slept in the hall near the door to the plaintiff's room. While the nurse was so sleeping, the plaintiff got out of her bed, passed through an open window, and fell to the roof of a porch below and injured herself. She brought this action to recover damages for the injuries sustained by her. There was no allegation in the petition, and there was no evidence to prove that the defendant did not exercise reasonable care in the employment of its physicians and attendants. The jury returned a verdict in favor of the plaintiff, and answered special questions to the effect that no one received profits or dividends from the earnings of the defendant; that the negligence of which the defendant was found guilty was in not complying with the special contract entered into with Mr. Davin in supplying a special nurse in constant attendance on Mrs. Davin at all times; that the special nurse placed in charge of Mrs. Davin was the servant or agent of the defendant guilty of the negligence found; that the medical superintendent and the special nurse had reason to believe that the plaintiff would be likely to injure herself; that the medical superintendent had been informed by a physician of the nature of the case. But the court holds that the plaintiff could not recover under the facts found by the jury, and affirms a judgment rendered for the defendant notwithstanding the verdict, which was set aside. The medical superintendent made the agreement, and he might be liable personally; but the plaintiff argued that because he failed to comply with his agreement the defendant was liable. But there was no reason why the defendant should be liable for the medical superintendent's negligence, any more than it should be liable for the negligence of the nurse who was looking after the plaintiff. Under *Nicholson* v. *Hospital Association*, 97 Kan. 480, 155 Pac. 920, wherein the court said that charitable associations conducting hospitals are not liable for the negligence of their physicians and attendants resulting in injury to patients unless it is shown that the association maintaining the hospital has not exercised reasonable care in the employment of its physicians and attendants, the defendant was not liable for the negligence of its medical superintendent.

Liability for Negligence in Case of Scarlet Fever

(Tadlock v. Lloyd (Colo.), 173 Pac. R. 200)

The Supreme Court of Colorado affirms a judgment for $400 damages in favor of the plaintiff for the alleged negligence of the defendant, a physician, in failing to give proper attention to the plaintiff's child, aged 5 years, resulting in the boy's death. The court says that evidence was produced to the effect that the defendant called as requested the first time, and diagnosed the disease as scarlet fever; that no instructions were given as to the care of the child, except that some pills were left with the mother to administer, with directions to bathe the child frequently, that the next day the defendant was requested to call and see the child again, but did not do so, saying that the disease must run its course; that on the day after that he was called on to visit the child in the morning, in the afternoon and in the evening, and on each occasion declined to make the visit, but later, after urgent request, went to the house, the child dying shortly after his arrival. From the testimony of a lay witness the child strangled to death from an accumulation of phlegm in its throat. A nonprofessional witness also testified that the defendant said, as he was attempting to remove the obstruction from the throat of the child, "It's too late; I ought to have come when you called me." On the other hand, the defendant introduced testimony contradicting specifically and in detail every material matter relied on by the plaintiff for a recovery of damages, thus making issues of fact the determination of which by the jury should not be disturbed by this court.

It was urged that even though the negligence of the defendant was established, there was nothing in the record to show that the death of the child was the proximate result of such negligence. But that the negligence alleged was the proximate cause of death was a question, under proper instructions, for the jury. The jury determined that the proximate cause of the death of the child was the negligence of the defendant; and, there being testimony tending to support that conclusion, this court should not interfere with the finding of the jury. It must be remembered that this case was not founded on active malpractice, but on the negligent failure to give proper care and attention to diagnosis and treatment of the patient. The plaintiff predicated his action on the theory that the defendant failed to inform himself and give proper attention to the case. There was no claim that the defendant did not possess skill, knowledge and experience in his profession, or that he made error in diagnosing the ailment. It was in no sense an error of judgment, but an absolute failure to attend on the patient and secure data on which to base any judgment, that constituted the ground of the complaint. There was abundant testimony that the defendant made no effort to inform himself of the condition of his patient, or the progress of the malady, and if damage resulted therefrom he was liable. In considering the amount of testimony to show that the death of the child was the proximate result of the alleged negligence, there must be taken into consideration the difficulty, if not the actual impossibility, of conclusively demonstrating the cause of death. The code of ethics among physicians is frequently a bar to securing positive testimony on questions such as were here involved.

An instruction was given that the fact that a physician was shown to have skill in his profession raised no presumption that he exercised such skill in a given case. This, if applicable, would probably have constituted error, for all persons are presumed to have properly performed the duties that are imposed on them by law, and this instruction deprived the defendant of such presumption. But it was to e noted that this action was founded solely on the fact that e defendant failed and neglected to attend on his patient, although urgently and repeatedly requested to do so. The case involved no question of skill or the exercise of skill by the defendant. *The instruction had no application to the case,* and the giving of it did not constitute prejudicial error.

*Nonspecific Therapy in Arthritis and Infections. D. M. Cowie and H. Calhoun.—p. 69.

Inverted and Diphasic P-Waves in Electrocardiogram.—According to Carter and Wedd the administration of digitalis may lead to an alteration in the negativity of the P-wave in Lead III of the human electrocardiogram. Three instances of the presence of a persistently inverted P-wave, in Lead III, uninfluenced by vagus pressure, atropin, digitalis or deep breathing are recorded. Excepting in the presence of a permanently negative P_3, the electrical negativity of the inverted P-waves in Lead III is reversed by atropin. Additional evidence is cited showing the effect of the vagi on a change in the location of the pacemaker in Lead III.

Epidemic Cerebrospinal Meningitis at Fort McPherson.—Ten cases of epidemic cerebrospinal meningitis were treated by Camac and Bowman, with two deaths. Kernig's sign was present in five cases, opisthotonos in three cases, orthotonos in two cases, delirium in six cases, headache in eight cases, and fever in eight cases (in four of these cases the temperature was 104 F. or more). The pulse was slow in comparison to the temperature, only one case showing the pulse above 103. Respirations were slightly increased. Vomiting was present in six cases. Lumbar puncture showed a cloudy fluid in seven cases; in three cases it was clear. A chill occurred in three cases. During the course of the disease the following findings were recorded: Serum sickness occurred in every patient treated except two, and one of these lived only four hours after his first treatment. The other patient was a negro, and he developed pain in ankles and testicles; there was no rash. Of the six cases in which *opisthotonos* was absent at the onset, it developed later in two. Orthotonos was a common feature. Of the five cases in which the Kernig sign was absent at the onset, it developed in two. Herpes labialis occurred in three cases. Purpura and rash, except that from serum sickness, was absent in all cases. The "spotted" rash described as one of the features of this disease did not occur in any of the cases. Three patients required catheterizing. All patients had a febrile temperature curve.

Goiter Among Draft Men From Northwest.—Among 8,951 men coming from certain of the northwestern states, notably Oregon and Montana, there were thirty-seven cases of goiter. The authors regard this as being a high percentage.

Nonspecific Therapy in Arthritis and Infections.—Following the injection of a foreign protein (typhoid vaccine) there is a sudden disappearance of the polymorphonuclear cells of the blood, which are soon replaced by an increase amounting in most cases to a hyperleukocytosis. The polynuclears are young and the presence of myelocytes and of nucleated reds points to renewed activity of the respective mesenchymal tissues. The foreign protein seems to have stimulated all the mesenchymal tissues simultaneously. The order in which they are usually called on in infectious processes is, first, the neutrophil leukocytes without immature forms; second, metamyelocytes; third, myelocytes; fourth, promyelocytes; and fifth, megaloblasts. Cowie and Calhoun are inclined to the opinion that during the leukopenia stage the polynuclears leave the blood stream and enter the tissues, and that the subsequent increase in cells is due to an overproduction of cells from the respective mesenchymal fundaments, as is witnessed by the presence of myelocytes and nucleated reds. This view is further substantiated by the clinical findings of increased joint heat and swelling. The temperature reaction and the clinical findings are not in the nature of an anaphylactic response, as is shown by the absence of an eosinophilia. The cyanosis observed is not due to methemoglobin. Improvement is most marked following those reactions in which there is a good myelocytic response. This is probably a measure of the capacity of the body to react. The marked similarity between the typhoid protein paroxysm and the malarial paroxysm causes Cowie and Calhoun to believe further that their production is due to a common etiologic factor—dead protein. The death of the malarial parasite sets free in the blood stream a sufficient amount of malarial protein to produce the typical protein reaction. The malarial paroxysm, therefore, is not due to the presence of the new organisms, as has been suggested, but to the death of the old ones.

Karell Cure for Heart Disease.—The modifications of this cure which Potter has employed are one or more of the following: (1) full milk (unskimmed); (2) strengthening full milk still further by adding cream but without increasing the bulk; (3) by adding lactose in gradually increasing amounts; (4) adding unsalted and very thoroughly cooked oatmeal in gradually increasing amounts, either to the milk itself as a gruel, or as a cereal on which the milk with or without lactose is poured. Numerous other modifications of this diet and many radically different diets, tried out in cases of cardiac insufficiency, have failed to produce the benefit almost invariably a result of the original and simplest form, namely, four times 200 c.c. of skimmed milk.

Potter is convinced that in many cases quite as prompt and efficient diuresis, loss of weight, disappearance of edema, and marvelous subjective improvement can be obtained with such modifications in the diet as suggested by him as in following the strict Karell cure. These modifications, if carefully adjusted to the individual taste, digestion and condition, do not disturb but rather aid the digestion. They also enable the physician to carry out, even in private practice, an excellent diet for the purpose in hand without arousing too great opposition. They permit a slower and more agreeable transition to a normal diet, as well as an opportunity to continue such a diet a longer period or practically to renew it from time to time, and that, too, more or less indefinitely whenever an increase of weight or of edema or a recurrence of dyspnea warns the physician of its expediency. Potter believes that this diet plus the rest entailed accords a valuable introduction to any reduction cure. One essential feature (if not the most important) is the almost invariably resulting decrease in the work of the heart.

Abdominal Cesarean Section.—McNeill has done forty-five consecutive cesarean sections, losing two mothers—one from acute dilatation of the stomach and one from general peritonitis—and four babies; three stillborn and one, a premature baby, died in three days as a result of the neglect of the attendant.

*Association of Certain Cutaneous Lesions with Diseases of Hemopoietic System. D. Symmers.—p. 1.
**Unusual Forms of Superficial* Epitheliomas of Skin. L. W. Ketron.—p. 22.
*Elephantiasis Vulvae. A. Ravogli.—p. 38.
*Syphilis of Tongue. G. D. Culver.—p. 484.

Symptomatic Relationship Between Skin Lesions and Blood System.—Symmers claims that instances of generalized exfoliative erythrodermia occur sufficiently frequently in association with such diseases of the lymph nodes as Cohnheim's pseudoleukemia, lymphatic leukosarcomatosis, Hodgkin's disease, mycosis fungoides and disseminated tuberculous lymphadenitis, as to indicate a symptomatic relationship. Symmers suggests that, in these circumstances, toxic substances formed in the lymph nodes are offered to the skin for excretion, interfering with its nutrition in such fashion as to promote widespread desquamation of the superficial epithelium. There are apparently excellent reasons for the belief that mycosis fungoides is primarily a disease of the hemopoietic system, more particularly the lymph nodes, in the course of which diversified skin changes arise, partly as phenomena secondary to the discharge of lymphotoxins or myelotoxins, or both, and partly as a result of infiltration of the skin by the same variety of cells as characterize the structure of the diseased lymph nodes themselves. A case is cited by Symmers in support of his contention that the clinical and pathologic changes in the so-called lympho*dermia perniciosa of Kaposi* are essentially the same as those of Sternberg's lymphatic leukosarcoma, both belonging in the category with cases of mycosis fungoides in which leukemic transformation occurs. And, Symmers says, the greater number of all cases of so-called sarcoid growths, as grouped and classified by Darier, are almost certainly nodular cutaneous tuberculomas. Therefore the term *sarcoid should be eliminated* from dermatologic literature as meaningless and confusing.

Unusual Forms of Superficial Epitheliomas.—Three cases of basal-cell epithelioma of the skin are reported by Ketron because of their unusual clinical appearances. One was a case of multiple epitheliomas of the back. *The lesions* presented the dark-red color characteristic of syphilis. One was a depressel, oval, scarlike epithelioma on the right cheek. The third was a large circular epithelioma situated just above the left breast. The lesion had a hard nodule in the center. These basal-cell epitheliomas occur as flat patches on the skin, spreading superficially, with little tendency to invade the deep layers of the corium. These patches lack the tumor formation and progressive ulceration characteristic of the usual forms of cancer. The only clinical sign which the lesions may show characteristic of the common forms of skin cancer is a raised, pearly border. This is, however, frequently absent and the diagnosis may be impossible without a histologic examination. *Ketron calls* attention to the fact that these superficial cancers are apparently insufficiently emphasized in textbooks.

Elephantiasis Vulvae.—Elephantiasis is described by Ravogli as consisting of a chronic hyperplasia of the connective tissues of the skin and of the subcutaneous tissues from a lymph stasis. The passive congestion causes the effusion of serum from the blood and lymph vessels together with white cells, which, infiltrating the tissue elements, produce hyperplasia and consequently disproportion of the parts. The same process affecting the papillary layer of the derma causes the proliferation of the papillae in the form of small warts on the elephantiasic surface. That syphilis is the most obvious factor in the production of elephantiasis cannot be doubted, although Wassermann tests, in some cases, have been slightly positive, and in others negative. Local applications have been of no benefit. The elephantiasic organs have to be removed. Ravogli has obtained fairly good results in all his cases; the patients have been seen again after two or three years, and relapses did not occur.

Syphilis of Tongue.—Among 530 instances of syphilis seen by Culver the tongue was involved in twenty-seven (5.09 per cent). There were sixty-two cases with mouth involvement, not including instances of syphilitic angina. Therefore the tongue was affected in nearly one half of the mouth cases, and in the greater proportion of the lingual cases the disease was limited to the tongue. There was one instance of lingual chancre, nine instances with mucous patches, eight with gumma, nine with chronic specific glossitis, including leukoplakia, four having leukoplakia associated with other phases of chronic specific glossitis. In the nine cases which were treated by Culver the duration of the condition was from one to nine years, an average of four. Three patients gave negative Wassermann reactions of the blood serum, four were positive, and in two the reaction was not determined. In all the nine cases there was an absence of epitheliomatous degeneration, whereas in eight instances of gumma of the tongue, with an average duration of two and one half months, there was an instance of complication with epithelioma. The most important conclusion reached by Culver is that with a doubtful tongue lesion it is not only a justifiable procedure, but it is urgently advised to administer arsphenamin.

Effect of Laundering on Lice.—The object of Moore's investigation was to determine to what extent laundering was destructive to both lice and eggs, and should it prove to be inefficient, what slight alterations could be made in the regular routine to make laundering effective. These experiments showed that the lethal temperature for lice is about 113 F. (45 C.) for twenty-two to thirty minutes washings, and a slightly higher temperature, 114.5 F. (45.8 C.) proved effective in fifteen minutes' time. The following procedure is recommended for the laundering of woolen goods to destroy both lice and eggs: Infested garments to be washed at a temperature of 120 F. (48.8 C.), not to fall below 115 F. (46.1 C.) during the washing period of fifteen minutes, this treatment to destroy the active stages without the use of any special chemicals. Garments are then treated in the regular manner until perfectly dry, when they should be placed in the hot air tumbler at a temperature of 150 to 170 F. (65.5 C. to 76.6 C.) for ten to fifteen minutes, resulting in the destruction of the eggs. By this method it will be possible to launder woolens without shrinkage, and destroy the lice and eggs without the use of a special chemical.

Influenza at U. S. Army General Hospital No. 17.—This epidemic was unique in that the original case from which all others developed was definitely known. A passing troop train consigned the patient to the care of Loomis and Walsh. The case was an extremely malignant case of influenza. The patient died. The necropsy showed bronchopneumonia of both lower lobes, the left being completely involved and the right to the extent of about 50 per cent. This patient had been carefully isolated. No one was allowed on the floor except the physicians, nurse and on the last day an attending corps man. The chief of the laboratory who saw him once to examine his blood manifested the disease the next evening. The medical chief who visited him was taken ill on the fourth day. The surgical chief saw the case only at necropsy, but came in contact with the chief of the laboratory all that day and the disease had fully developed on the next day. The nurse who attended the first patient showed definite symptoms on the fourth day. All four of these cases showed the typical signs of influenza and later bronchopneumonia, the chief of the laboratory dying and the other three patients passing through severe sieges and recovering. The disease spread to nurses and attendants, and it also developed in eighteen enlisted men and three tuberculous patients. Of these thirty-one patients, pneumonia developed in eight. All but one of these eight had been in direct contact with the original patient or with the chief of the laboratory, both of whom died. All physicians, nurses and enlisted men who came in contact with patients wore masks and gowns, and were carefully instructed in regard to precautions, though evidently without avail. Doctors, nurses and attendants helped to feed the flames and fill the wards until an immune staff was found. It is interesting to observe that out of 200 tuberculous patients the disease developed in only three while twenty-eight cases occurred among the personnel of 100.

Backache from Medical Viewpoint. M. S. Woodbury.—p. 18.
*Syphilis As Cause of Backache. P. W. Roberts.—p. 20.

Etiology of Nephritis.—Only such cases were *studied* by Hunt in which there were well defined evidences of focal infections and of renal involvement which suggested diffuse hematogenous inflammatory lesions or nephritis with fibrosis.

The influence of metallic or other toxins, except chronic foci, has been excluded in every way possible and the alteration of functional power before and after the correction of discoverable foci has been used as a criterion for diagnosis and as indicating chronic foci as the most important etiologic factor. In order to standardize each case immediately after the history and physical examination had been made, the patient was placed on a nephritic test diet, containing approximately 13.4 grams nitrogen, 8.5 grams sodium chlorid and 1,800 cubic centimeters of fluid during each twenty-four-hour period. Patients were not permitted to have eliminating baths, cathartics or enemata during days of observation. The meals were served in the room by a specially selected waitress and all foods and fluid not ingested were returned to the diet kitchen for remeasurement. By this means a more careful check was made of endogenous nitrogen and sodium chlorid. A specific gravity fixation test, a phenolsulphonaphthalein test, total nonprotein nitrogen determinations of the blood and of the urine were made. Ammonia nitrogen and chlorids from the urine and blood plasma chlorids were determined. Plasma acidity and blood sugar determinations were also made. The full details of all these tests and analyses are given in the original article, which should be consulted.

Of 342 cases of nephritis presented, sixty were studied by the methods noted. Of the sixty, forty-seven submitted to corrective measures as advised and were subsequently restudied. The longest period of observation was two years and the shortest twenty-six days following corrective measures. Of the forty-seven patients submitting to correction measures, nine have not been noted, six report little or no change, and thirty are "much improved" or "apparently as good as ever." Hunt says that the latter quotation appeared frequently enough to be used as a general statement. Culture studies showed a *Streptococcus nucosus* as the principal pathogen. Other bacterial forms, in order of frequency, were a diphtheroid, *B. mitis*, *S. candidus*, *S. viridans* and pneumococcus (not typed).

Inherited Syphilis as Cause of Backache.—The five cases of back pain observed by Roberts in this study fall under the general classification of myositis. Their symptomatology suggests irritation of muscle and fibrous tissue by some toxic material, and the degree of discomfort ranges from dull lumbar backache to acute pain on any attempt at motion. Except for tenderness on deep pressure in the gluteal and lumbar regions no characteristic features have marked these cases. These patients had been treated for a variety of disorders, including uterine displacements, sacro-iliac strain, Potts' disease, scoliosis and floating kidney, and in one woman a diagnosis of carcinomatosis was made. While Roberts has not been able always to demonstrate the presence of syphilis in these patients the fact remains that they all presented certain evidence of an hereditary taint and that the symptoms cleared up under mixed treatment.

Chronic Ulcerative Colitis.—Logan shows that all forms of treatment of chronic ulcerative colitis are thus far unsatisfactory. The best results come from dieting and giving surgical rest to the colon, except in cases in which the condition is localized to the lower bowel within easy reach of enemas. Hyperemia of the bowel obtained by the use of hot water (120 F.) gives the best results to date. After the cure of the ulcer is obtained, marked deformity and stricture of the bowel remain permanently.

Treatment of Gunshot Wounds of Lung at Front.—Duval claims that of gunshot wounds of the lung, the general mortality in the advanced ambulances and in the hospitals of evacuation was on an average 30 per cent., this percentage not taking into account a large number of deaths which occurred in the advanced posts and in the base hospitals. The predominant causes of death were: hemorrhage, mechanical troubles of respiration from open thorax, and, above all, infection of the lung and pleura. Duval emphasizes that a gunshot wound of the lung presents exactly the same lesions as does any other war wound, and is subject to the same evolution. A lung wounded by a fragment of shell is always contaminated and later on infected by the same anaerobic germs which infect all war wounds; e. g., *B. perfringens*, *Vibrion septicus*. There are also often present streptococci, as well as those organisms which are the normal inhabitants of the bronchial passages. A wound of the lung has the same period of infection as any other wound. Associated with it, however, is a serious complication; namely, infection of the pleural cavity.

Duval's statistics from the Battle of the Somme where, excluding operations of urgency, cases were treated medically, show a mortality of 20 per cent. in 300 cases. In a later series when the operative treatment was employed, eighteen cases were operated out of 118 and no deaths; 100 cases treated immediately with one death from empyema. In a total of 136 cases—118 not urgent and 18 urgent—the general mortality was 9 per cent. It will be seen, therefore, that surgical treatment lowers the mortality very considerably. What is more, when septic complications do occur, they are less serious. Surgical treatment of the lung should, therefore, be considered as the logical prophylactic procedure to prevent sepsis.

Artificial Pneumothorax in Treatment of Chest Wounds.—Bastianelli reports on the use of artificial pneumothorax in cases of chest wounds. Of 290 penetrating chest wounds, there were with closed chest, 206. Of these 206 patients, 88 were treated by pneumothorax, and 118 by thoracocentesis and pneumothorax, with a mortality of 7 or 3.4 per cent. Of these, 3 were due to empyema, 1 to pulmonary abscess, 3 to septicemia. Of 84 cases of open chest wounds, 19 or 22.6 per cent. terminated fatally. Of the 19 dead, 1 patient died before reaching the hospital, 7 patients had bled and were shocked so severely that nothing but, perhaps, transfusion could have helped them. Subtracting these 8 cases, there remained 76 in which the treatment could be tried. In these 76, there were 11 deaths or 14.4 per cent. Of these, 7 were due to empyema, 4 to septicemia. Empyema occurred altogether 11 times but only in the cases treated by permanent closure of the parietal wound with the rubber bag. Since this procedure has been resorted to for emergency only and the wound has been sutured airtight according to Bastianelli's principles, only 2 deaths or 5.7 per cent. occurred in 35 cases.

Early Treatment of Gunshot Wounds of Chest.—The principle to be aimed at in the treatment of these cases, in Gask's opinion, is the early mechanical cleansing of the wound, both of the chest wall and of the injured viscera, the evacuation of all foreign bodies and of effused blood from the pleural cavity; the repair or suture of the damaged lung and the closure of the chest cavity by suture.

Operation in Later Stages of Gunshot Wounds of Chest.—The indications for operation in these late cases laid down by Turner are: 1. Foreign bodies in the parieties with or without sinuses. 2. Foreign bodies in the lung irrespective of size if associated with persistent cough, hemorrhage, or suppuration. 3. Large foreign bodies in the lung, even if the symptoms are purely nervous. 4. All foreign bodies lodged in the pleura with or without empyema. 5. All cases of infected hemothorax. 6. All cases of through-and-through wounds with shrinking of the side, lessened lung expansion, and interference with movements of the diaphragm in which treatment by exercises, etc., has failed.

Early Treatment of War Wounds.—The basis of all successful treatment of wounds, Gask says, is early mechanical cleansing by surgical operation conducted under aseptic precautions. By this is meant the removal of all dead or damaged tissue, together with all foreign bodies such as the missile, portions of clothing, or splinters of wood. If this is done and is followed by closure of the wound either immediately by "primary suture" or a few days later by "delayed primary suture," then a very large percentage of wounds heal by first intention, with a resultant saving of a great many lives and an immense reduction in the period of convalescence, labor of medical officers and of dressing material. The important thing is that a wound should be subjected to a complete, early, mechanical cleansing before organisms have time to multiply and invade tissues. If this is done, Gask says it matters little whether a wound is swabbed with ether, flushed with Carrel-Dakin solution, smeared with "bipp" paste, or packed with flavine. As long as the wound is cleansed mechanically and no more organisms are put in, then the wound will remain clean and may be closed at an early date.

Acute Perforations of Abdominal Viscera.—Mayo's experience has convinced him that a considerable percentage of free perforations are spontaneously closed and that the area of peritonitis is limited through natural processes; the death rate is possibly about 30 per cent. but the 70 per cent. of patients who may recover spontaneously from the attack are not cured. An exploration through a longitudinal incision just to the right of the midline gives the surgeon an opportunity to make a careful exploration and to deal with any or all varieties of perforation. Early operation, that is within the first eight hours, barring accident, means recovery, because the stage of contamination has not yet passed on to infective peritonitis, and measures may still be taken for the permanent cure of the condition which leads to the perforation. Chronic conditions usually precede perforation and give ample warning of their presence before it takes place. While this is accepted, so far as the appendix is concerned, it has not been so generally recognized that gallstones are foreign bodies which need only infection to lead to the most widespread peritonitis, cholangitis, biliary cirrhosis and pancreatitis. Chronic ulcers of the stomach and duodenum, after a reasonable attempt has been made at medical cure, should be looked on as surgical maladies.

Torsion of Great Omentum During Pregnancy.—Bubis believes that his case was probably an adhesion of the tip of the omentum to the culdesac. The pressure from the growing uterus and the peristaltic action of the intestines, together with the congestion of the veins of the great omentum, were undoubtedly secondary causes of this condition. A localized point of tenderness, normal temperature, pulse and respiration, and the absence of nausea and vomiting in the early stages of pregnancy, are pointed out as constituting a group of symptoms very suggestive of torsion of the great omentum. One hundred and thirteen similar cases are recorded in the literature.

Duodenectomy: Transplantation of Pancreatic Duct.—Grey's experiments demonstrate, first, that the major pancreatic duct can be transplanted successfully into the jejunum. Many months subsequent to this operation nothing abnormal was made out in the microscopic or the gross architecture of the pancreas, except a dilatation of the duct, most apparent in the third portion proximal to the intestine. The ostium at the lumen of the bowel remains patent. Second, the biliary and the pancreatic secretions may be diverted successfully from the duodenum into the upper jejunum. The withdrawal of these alkaline juices from the duodenum must profoundly affect the chemistry of duodenal digestion, since peptic ulcers not infrequently decelop here under such condition. The subsequent resection of the duodenum and the suture of the jejunum (which now receives the pancreatic juice) to the stomach eliminates this complication. Third, it is apparent from the protocol of the duodenectomized animals that it is possible to resect the duodenum—every trace of mucosa and approximately all of the muscular coats—without embarrassing the vascular supply of the adjacent pancreas. This accomplishment does away with the necessity of excising the greater portion of the gland, a recourse to which Minkowski was forced to turn when he sacrificed the pancreaticoduodenal vessels with the duodenum. Fourth, success can only be looked for in excising the duodenum and carrying out the reconstructive steps when the operation is divided into a number of stages, leaving an interval of several weeks, at least, between the successive steps of the procedure.

Grey's experiments afford indisputable evidence that the presence of the duodenum is not essential to the life and comparative good health of a dog, at least for nine and one-half months, provided that the pancreas and the liver continue actively to discharge their respective secretions into the gastro-intestinal tract. From these considerations, then, it is evident that the conclusions of Stassoff regarding the inability of the remaining portion of gastro-intestinal tract to compensate for the loss of the duodenum are not substantiated by experiment.

Operation for Hypertrophied Prostate.—Wright's objection to doing suprapubic cystotomy as a preliminary to a prostatectomy is that if the patient becomes uremic after having established continuous drainage by cystotomy, one cannot refill the pelvis of the kidney and replace the kidney tubules to the abnormal position under which they formerly functionated. On the other hand, by doing preliminary drainage with a catheter, if the patient begins to show signs of uremia, one can withdraw the catheter and in a few hours the pelvis of the kidney will refill and the kidney tubules, being replaced to their abnormal position, will again functionate. The cause of death is the sudden emptying of the renal pelvis. Wright says that cystotomy should be reserved for use in those cases where catheterization, for any reason, is impossible; or, for use in those cases of acute cystitis that do not do well with a permanent catheter. If compelled to do a cystotomy, it should only be performed after catheterization or aspiration of the bladder has been carried on for several days.

Vascular Changes in Massive Syphilitic Splenomegaly.—Symmers and his associates report on the results of examination of six spleens. The variety of splenomegaly described was encountered in syphilitic subjects only. In the splenic substance were visible variable numbers of *pinhead-sized*, rounded, oval, or angulated bodies with a brownish or yellowish brown, granular looking center, and with or without a peripheral zone of red cells. These bodies which correspond, histologically, to sclerosis and mineralization of the smaller arteries, are characteristic and readily identified, and are distinct from anything familiarly encountered in the naked eye examination of the spleen. The substance of the spleen presents a reddish, flesh-like appearance, is leathery in consistence, and shows, on section, numerous small vessels whose walls are pale and thickened, correponding, microscopically, to venules in or around which hyaline deposits have occurred, but which are immune from infiltration by mineral salts. Hemorrhages may be seen by the naked eye and, histologically, are found in various stages of organization. In addition, the splenic substance is extensively replaced by the productive overgrowth of connective tissue of inflammatory origin.

Carcinoma of Stomach.—In each of the three cases reported by Douglas resection of about one third of the pyloric end of the stomach was done. The first case is of special interest because, notwithstanding the presence of a tumor of which the patient was herself conscious for eighteen months before operation, and although microscopic examination demonstrated scirrhus carcinoma, the tumor was not adherent to the surrounding parts, the operation was not technically difficult, and the lymph glands in the pyloric regions, although enlarged, were not the seat of malignant metastases. The second case presented several unusual conditions. First, the age of the patient, 30, which is rather an early age for the appearance of carcinoma of the stomach. Second, the proof, both from the history and the pathologic findings, of the development of carcinoma in the edge of a pre-existing ulcer. Third, the evidence of an old perforation which had been closed by adhesions to the liver, the capsule of which formed part of the new base of the ulcer. Fourth, the technical difficulty of the stomach resection, necessitating a resection of that part of the liver adherent to the base of the ulcer. The chief interest in the third case was the age of the patient, 71 years. This case also demonstrated that although the patient may be emaciated and weakened as a result of the pyloric obstruction, in the absence of metastases, age is not necessarily a contra-indication to a radical operation.

Simple and Expeditious Method of Performing Abdominal Incision.—In this method the gloved hands of the surgeon and his assistant, protected by gauze pads take the place of retractors and clamps. Complete protection against skin contact is said to be afforded.

Operation for Incontinence of Urine.—Young does a plastic operation on the internal and external sphincters in cases of incontinence of urine of long duration in which both internal and external sphincters have been destroyed by previous operative trauma.

Simple Method of Draining Bladder.—Martin uses a large catheter and a piece of rubber tubing, one-half inch in diameter, long enough to reach from the fundus of the bladder to a point 1 inch above the skin. Several small holes are cut in the tube near the end to be placed in the bladder, and one at the level of the skin, large enough to insert the catheter snugly so that the urine will not escape. The catheter is pulled through this opening to about one-half inch from the bottom of the large tube, the tube is introduced into the bladder and the wound closed tightly around it. As soon as the urine rises in the tube above the point where the catheter is inserted, it will prime the catheter and empty the bladder.

*New Roentgen Ray Unit (Rad) in Roentgenotherapy. S. Russ.—p. 226.

New Roentgen Ray Unit in Roentgenotherapy.—The unit proposed by Russ is that quantity of roentgen rays which when absorbed will cause the destruction of the cells in question, and the name suggested for the unit is the Rad. The photographic action of the rays which are being administered to the patient is obtained on a photographic plate; on the same plate is impressed the photographic effect of a standard source of radiation; for convenience this is a capsule of radium emitting beta and gamma rays. The plate is developed with any developer, and with no restrictions as to time or temperature—any of these variables will affect the roentgen ray and the radium units to an equal degree; a comparison is then made between the photographic impressions so obtained. Assuming that the roentgen-ray tint for an exposure of ten seconds was equal to that obtained with an exposure of six seconds with the radium. The radium capsule, when applied to malignant cells, causes complete inhibition of their proliferation after an exposure thereto for one hour; this latter quantity is the suggested unit, namely, the Rad. Hence, the dose of roentgen rays at the position occupied by the plate during the ten seconds' exposure would be 1/600 Rad. Supposing that during a seance the tumor cells had been exposed for twenty minutes to the above intensity of roentgen rays, the dose received would be $\frac{20 \times 60}{10} \times 1/600 = 1/5$ Rad.

Pulmonary Spirochetosis.—Having found spirochetes in considerable numbers in the sputum of one patient, Thomson systematically examined the sputum of all patients complaining of coughs by simple stains and by the special stain for tubercle. He found that pulmonary (or bronchial) spirochetosis in a chronic form was apparently prevalent among this group of patients. Seventy-nine patients were examined; thirty-nine showed spirochetes and in two cases tubercle bacilli were present. Some of these cases simulated tuberculosis, others malaria. So far as could be ascertained from the physical signs, which were always of an indefinite character, there appeared to be no serious pulmonary lesions.

Operation for Excision of a Cartilage.—From Hammond's observations it would appear that soldiers do not do as well after this operation as do civilians. The average stay in hospital following an operation of the excision of a cartilage is in the case of civilians three weeks; in four weeks the patient is again back at work. It has become increasingly evident that the prognosis in the case of soldiers is not nearly so good.

Camphor in Acute Influenzal Bronchitis and Bronchopneumonia.—Giuseppi treated 250 cases with camphor, with a mortality of one—a man who died after three days' illness from bronchopneumonia. The incidence of bronchopneumonia in the 250 cases was twenty-six, or 10 per cent.; in another series of 200 cases during the same outbreak, and untreated with camphor, the incidence was 8 per cent., but the number of deaths was four, a mortality of 2 per cent. The treatment adopted was the administration of pills containing 4 grains of camphor made up with soap, in mild cases three times daily and in the very acute cases every three hours. The treatment was continued until the temperature dropped and the signs of bronchitis or bronchopneumonia cleared up.

Influenza and Its Complications.—It is Muir's and Wilson's belief that Pfeiffer's bacillus plays a very important part in the production of the characteristic lesions of influenza.

After-Results of Stomach Operations.—In Stretton's series of 175 operations there were twenty-one cases of perforation of the stomach or duodenum. Ten of these patients were saved from death and only in one instance was there a recurrence. In the case of the eleven who died, perforation had existed for more than twenty-four hours when first seen. The gastro-enterostomy operations number 116. Some were performed with the object of giving temporary relief in cases of malignant disease, but the majority were for the purpose of establishing a new route for the exit of food into the jejunum, because the pylorus was partially occluded. In two cases the operation was performed for the relief of symptoms due to hourglass constriction of the stomach. In another case Stretton excised the hourglass constriction. The results in all three cases were equally satisfactory. Hence, Stretton prefers gastro-enterostomy since it is a far less serious operation than excision. The immediate mortality in this series of cases is 2 per cent. There were twelve cases of stomach cancer. One of these patients was operated on for carcinoma of the pylorus (partial gastrectomy). She is alive and well after 15 years.

Valvular Disease of Heart.—Rudolf cites a case of aortic incompetence, and possible stenosis, and of mitral leakage and probable stenosis in a soldier, aged 25, who not only stood the stress of active service in the front line for years and was at last only invalided on account of gassing but actually outrivalled all his fellows as an athlete. The case emphasizes the correctness of the view that has so often been urged in recent years by Sir James Mackenzie and others, that everything depends on the state of the heart muscle. This patient had evidently an exceptionally strong and sound myocardium.

*Variability of Paratyphoid Bacilli. M. Maruta.—p. 1.
Bone-Grafting in Surgery. K. Kuroiwa.—p. 2.

Variability of Paratyphoid Bacilli.—Maruta, working in Kure Naval Hospital in 1917, proved in the case of a patient discharging paratyphoid A bacillus in his feces, that an abnormal type of that bacillus began to be discharged along with the normal type, after the clinical signs had entirely disappeared. He could also isolate two types of bacilli discharged in the feces of a carrier of paratyphoid B bacillus. The duration of the discharge in the feces of the abnormal paratyphoid A bacillus was about one month, while the corresponding type of paratyphoid B bacillus continued to be discharged for six months. Both abnormal types of paratyphoid A and B bacilli had many common features. Serologically there was no difference between the normal and abnormal types. Maruta suggests that these abnormal types were developed from the normal ones which invaded the gallbladder of the patients; and, consequently, patients discharging these abnormal types may be regarded as permanent carriers. Experiments made to get the normal types from these abnormal ones, by passing the latter through animal bodies are unsuccessful.

Influenzal Septicemia.—As to the pneumonic incidence in influenza cases, Abrahams and his associates found that out of 1,000 cases of "influenza" upward of 800 have taken an ordinary simple uncomplicated course with fairly speedy recovery and without sequelae. The remaining 200 have become more or less pulmonary; of these, perhaps, eighty being of moderate severity; the remaining 120 patients have been desperately ill; of these latter somewhere between sixty and eighty have died. In these latter cases the essential feature is an infection by *B. influenzae* with a secondary infection by some other organism, the pneumococcus, *Streptococcus pyogenes-longus*, or a "diplostreptococcus," the virulence of which appears to be exalted by the initial influenzal infection. The characteristic features of the septicemic type of case are variable lung symptoms, ranging from slight bronchitis to lobar pneumonia, very characteristic heliotrope lividity, dyspnea, or rather polypnea, and very rarely orthopnea. Infection takes place in the upper respiratory passages, and involves the accessory nasal sinuses, where a septic sinusitis develops. From this and possibly other foci as yet undermined, the toxemia or septicemia originates. In view of the large number of instances in which the diplostreptococcus has been isolated in pure culture from the heart's blood and internal organs immediately after death, it is concluded that this organism plays an important rôle in the fatal cases. The large majority of cases of septicemic type terminate fatally in spite of any form of treatment. Patients have recovered who have been given no specific treatment of any kind.

B. Multifermentans-Tenalbus in Gas Gangrene.—This bacillus was isolated by Stoddard from a case of gas gangrene of the arm which recovered promptly on excision of infected muscle. There appeared to be a production of lesions with *B. sporogenes* and *B. multifermentans* in combination which were not produced with larger doses of either alone. In one case death was produced in twenty-four hours. The lesions, as a rule, appeared to be local, consisting in swelling and tenderness for a short period and in a muscle infection for one to three days. *B. multifermentans* alone in moderate doses seems to be nonpathogenic; with *B. sporogenes* both become able to cross the threshold of the animal's resistance, but do not give extensive lesions. The morphology and cultural characteristics of this bacillus are described in detail.

Lemon Juice Residue in Infantile Scurvy.—Four cases of infantile scurvy are cited by Harden and his associates in which they used the residue of lemon juice from which the free citric and other acids had been removed. This preparation can be concentrated in bulk to any desired volume, or even evaporated down almost to dryness without losing its potency as an antiscorbutic. The almost complete elimination of the acids from the fruit juice removes or diminishes its irritant property, and the concentration of bulk makes it possible to give much larger quantities of the antiscorbutic factor than has hitherto been practicable. The outstanding feature of this treatment was the use for the first time clinically of the antiscorbutic factor separated from the greater part of the inactive components of the foodstuff in which it occurs. Moreover, this antiscorbutic factor was given in concentration at least double—in one case seven times—as strong as that in which it occurs naturally in the foodstuff (lemon) from which it was obtained. The treatment was thus, so to speak, "intensive." The result was found to be extremely rapid amelioration of the symptoms.

Version in Midwifery. M. Culpin.—p. 529.

New Operation for Bicornate Uterus.—In the case cited, which was one of double uterus with a certain amount of fusion of the cervices and lower part of the bodies only, McArthur cut out completely somewhat less than the inner half of the cervices, the incision extending through anteroposteriorly, leaving the outer halves of each cervical canal. The posterior edges of the right and left cervical canals were then united, as were the anterior edges, making one cervix and one cervical cavity. Intra-abdominal operation was then undertaken, and here a congenital defect was found. The mesentery of the sigmoid flexure had continued from the pelvis, and was attached between the juncture of the two uterine bodies. This was not an adhesion, but a definite mesentery. McArthur suggests that perhaps this congenital defect had prevented the müllerian ducts fusing in their upper segments during fetal life. This mesentery was removed by dissection and was replaced in a normal position. An incision was then made clear across the fundi of both uteri down into their cavities. A portion of the septum remaining between the two uterine bodies that had not been reached by the vaginal route was excised and the endometrium of the two halves was curetted. The two uteri were then sutured together just as one would sew up the two halves of a split uterus, and when the stitching was complete, the uterus presented an absolutely normal form, appearance and size.

*Experimental Purpura Hemorrhagica Produced by Antibloodplatelet. T. Watabiki.—p. 47.

Experimental Purpura Hemorrhagica Produced by Antibloodplatelet.—The most interesting result of Watabiki's investigation was the fact that the subcutaneous injection of antibloodplatelet into animals produced typical purpura hemorrhagica, but guinea-pig's antibloodplatelet acted on guinea-pigs only. For isolating bloodplatelet, Watabiki found sodium citrate glucose salt solution best adapted to the purpose. Intraperitoneal injection caused a violent reaction producing typical purpura hemorrhagica, the animals dying in sixteen hours to four days. Intrapleural injection produced the same symptoms. Intravenous injection of antibloodplatelet caused instant death of the animal, and no peculiar symptoms could be observed on its dissection. Antibloodplatelet injection in excess of a fatal dose into an animal that was previously immunized by antibloodplatelet caused no change, but when the same quantity was injected into a normal animal it caused the death of the animal and showed purpura hemorrhagica on necropsy.

Emphysema of the Mediastinum.—Achard's research on dogs seems to show that mediastinal emphysema is merely part of a more extensive cervicothoraco-abdominal emphysema.

War Wounds of the Eyes.—De Lapersonne reviews the experiences with war wounds of the orbit at the Hotel-Dieu at Paris, a total of 2,449 cases. See Paris Letter.

Changes in the Blood During Malarial Attacks.—Barbary comments on the great destruction of reds and of the hematoblasts during the attacks of malaria. The resulting anemia is a chlorosis, the toxins of the disease inducing intense hemolysis at each attack. In treatment, therefore, it is important to supplement the action of quinin by measures to aid in the regeneration of the blood. The most effectual in this line, in his experience, was colloidal iron. In tenacious cases he gives this with the quinin in intravenous injections, on alternate days, without heeding the hours of the attacks.

Postinfluenzal Purulent Pleurisy.—Bérard and Dunet insist that pleurotomy is indicated in every case of this kind in child or adult. The incision in the eighth or ninth interspace to evacuate the pus allows introduction of the finger to determine the lowest point of the pleura as the patient lies semireclining, the usually preferred posture. In this position the lowest point is in front, and he makes an incision here (or extends the first incision), resecting the eighth or ninth rib at the anterior axillary line. After resection of the rib, the pleura is incised where the finger within makes it protrude, at the lowest point. What is left of the pyogenic membrane lining the pleural cavity has to be removed in toto; this can be done by swabbing out the pleural cavity with a sponge held in long forceps. This second incision can be postponed to a few days later if the condition is grave. One or two large drains are placed in the anterior incision. Twenty-four hours afterward Carrel tubes are introduced through the first incision and the pleural cavity is flushed every three hours with a small amount of some antiseptic solution under weak pressure. This irrigation is kept up for eight or ten days. After this the irrigation can be continued at need, using merely a syringe. The patient is got out of bed as soon as the temperature is normal, by the third or fourth day, as a rule. He is ordered to walk about the room regularly. This ensures better expansion of the lung, expansion of the chest, and perfect drainage. In twenty-two cases in which this *méthode ambulatoire* was applied, the results were extremely gratifying except in two cases in which the preexisting pneumonia proved fatal. The others were completely healed in fifteen, twenty or thirty days, according as the pneumococcus, the staphylococcus or the streptococcus was involved. There was no loss of weight and no deformity of the chest. The clearing out so completely of the pus prevents absorption of toxic substances, and the patients are left in good condition, gaining instead of losing in weight.

Chronic Lumbar Rheumatism. A. Léri.—p. 471.

Recurring Hydrarthrosis of the Knee.—Tavernier comments on the difficulty of ascertaining the cause in these cases, and reports instances in which the trouble was traced to an unsuspected foreign body in the joint or a synovial fringe or some lesion of the meniscus. One young girl, after a runaway accident, suffered constantly in the knee for a year but there was no apparent reaction in the joint nor atrophy of muscle. A minute fringelike projection on the meniscus was removed, and this materially reduced the pain without curing it completely. The pains in these puzzling cases spread through the whole knee and the joint may be tender throughout. He has operated in only four of his fifteen cases of dislocation of a meniscus. In two of the cases he removed the whole meniscus, as it was rough. The knee now in these two cases is indolent and there is no effusion. In complete extension the knee is solid, but when it is flexed there is a slight sideward movement but the joint is strong and serves perfectly in long walks and at the trade of cabinetmaker. Supervision of his cases for several years has shown that unless one's hand is forced by serious disturbances, it is better to advise the patients to wait, after a luxation, avoiding abrupt and violent movements, and lying down for a few days. Massage of the thigh muscles is useful to ward off atrophy, but he has seen very bad results from local massage, exacerbation of the pains, and return of the hydrarthrosis. The patients say that rest relieves, while mobilization and massage aggravate the pains.

Diagnosis of Cancer in Rectum and Terminal Colon.—Bensaude asserts that scarcely a fortnight passes in which he does not encounter some case in which palpation or endoscopy does not reveal some previously ignored cancer or correct the diagnosis of cancer. Some patients were being treated for cancer when the trouble was merely amebic dysentery, or an inflammatory tumor, or simple hemorrhoids proved to be responsible for anemia ascribed to a cancer. In other cases the symptoms of tabes had been attributed to cancer. Simple congestion has been mistaken for cancer; the awkward introduction of the rectoscope having caused bleeding. But the inverse error, the mistaking of a cancer for some comparatively harmless lesion is much more common, especially the diagnosis of hemorrhoids or enterocolitis, when the disease is really malignant. In his private practice alone, he has encountered in the last five years sixteen cases of cancer mistaken for enterocolitis, and given long courses of treatment on this basis. The age is no criterion; he has had a case of cancer in the rectum in a girl of 19, and Quénu has reported cases at 21, 28 and 30. The general condition is not necessarily impaired, and the patient may even gain in weight.

Nothing is more obscure, he says, than the early stage of cancer of the rectum or colon. There may be absolutely nothing to call attention to the region. Even if diarrhea or tenacious constipation attract attention, the disturbance is usually located by the patient in the upper abdomen; he complains of flatulence and of pain around the umbilicus. Others complain of pain in the groin; in one case the man was being treated for rheumatism. Disease in the lower bowel renders the patients irritable, hypochondriac, and may deprive them of sleep—all of which sustains the assumption of nervousness. With endoscopy, adherent feces may mask the lesion. In one case an abscess concealed the cancer. Masking folds can be smoothed out by insufflation, or they can be altered by a change of position. When a minute cancerous nodule is found, it should suggest a primary cancer above. The cancer may be of the ulcerative or infiltration type. The latter is common with metastatic cancer; the primary growth is usually in the stomach and there are probably other cancerous growths along the *intestinal tract*. As positive findings *with endoscopy* are so instructive, examination may well commence with this, but *no* other means of examination should be neglected in dubious cases, radioscopy, palpation, a flexible probe, examination of stools, etc.

Pain and Ulcer in Stomach Secondary to Appendicitis.—Roux analyzes some American works of the last few years on the pains in the stomach and ulceration at the pylorus or in the duodenum, all secondary to acute, subacute or chronic appendicitis. In three of Roux' own cases of the kind the pains came on at once after eating anything. The epigas- trium may be constantly tender. The pains may not develop until several hours after eating, but there is *no such* regu- arity of the time as with ordinary ulcer, and eating some- thing does not relieve them. In another group of cases, actual gastric or duodenal ulcer develops a few days or months after an attack of appendicitis. In this type of cases, removal of the appendix does not cure all disturbances, as is the case *with the merely painful gastropathies* just mentioned. Some slight lesion in the mucosa allows an ulcer to develop in addition to the reflex disturbances responsible for the painful gastropathies. The irritation of the solar plexus from the appendicitis probably induces reflex spasm of the pylorus and may modify gastric secretion.

Resection of Gastric Ulcer.—Carnot's arguments present a good plea for resection of the ulcer as gastro-enterostomy alone does not ward off the danger of hemorrhage, perforation and malignant degeneration. Even resection, however, does not guarantee absolutely against these, although materially reducing the danger. It should be supplemented by prolonged medical treatment and dieting.

Surgical Treatment of Gastric Ulcer.—Pauchet states that half of all cancers in the human are in the stomach, and three-fourths of them are grafted on old chronic ulcers. With most of these there never were any characteristic symptoms, or the symptoms were mild and occurred only intermittently and at long intervals. He gives an illustrated description of the various technics that have proved most successful with the different kinds and locations of ulcers. Among the minor points he emphasizes are the necessity for swabbing the sutures with tincture of iodin before burying them; the use of OO catgut for the perforating sutures; changing gloves before suturing the wall; never forgetting to close the breach in the mesocolon, and always handling the tissues gently, never pulling on them or crushing them.

Treatment of Chronic Amebic Dysentery.—Carles admits the marvelous efficacy of emetin in acute amebic dysentery, but says it has relatively little action in chronic amebiasis. For this emetin and bismuth iodid seems to be preferable. It is important, however, to free the patient of any other helminths he is harboring, as even this drug is useless when there are other parasites besides the ameba. The specific treatment should be supplemented by treatment of the gastro-intestinal secretory insufficiency, gastric neurosis and enteritis from fermentation, if they are associated with the amebiasis. Chronic amebic dysentery has to be combated with chronic treatment; even if the cure seems complete, successive courses of the iodid are indispensable.

Lumbar Puncture with Skull Wounds.—Bouttier and Logre discuss the unilateral vascular disturbances liable to follow injury of the brain. These disturbances may be favorably modified by lumbar puncture. This throws light also on diagnosis and prognosis, and on the etiology.

Rheumatoid Purpura.—Lavergne reports three cases in children from 5 to 12 years old, in which intense gastro-intestinal disturbances and melena were traced to rheumatoid purpura. When a child over 5 develops abdominal pain, with or without vomiting, the possibility of rheumatoid purpura should always be borne in mind, and the eruption should be sought for, especially on the legs near the malleoli where it is usually most intense. Even if *no eruption* is discovered, the diagnosis should be long expectant before *excluding* purpura definitely. In the first case, sudden and lively pain in one knee and in the abdomen were the first symptoms. By the next day there was severe pain in the wrists, and the following day there was melena and a purpuric eruption on the legs. Then all the symptoms rapidly disappeared, but the fifteenth day the purpura alone returned. By the end of the fifth week the condition seemed to be entirely normal once more. In the second case the abdominal pain and occasional vomiting had kept up for a month, but there was nothing to call attention to any of the joints. About the thirty-third day a slight eruption on the legs confirmed the assumption of purpura. It was so slight that it would have been overlooked if it had not been sought with special care. *In such* cases appendicitis is suspected, and if there is blood in the stools, melena or invagination is accepted. Palpation is so painful that the child will not allow it. In the third case only the elasticity of the abdominal wall spoke *against* appendicitis. As there was no eruption and no pains in joints, the diagnosis wavered only between chronic *invagination* and duodenal ulcer. The green fecaloid vomit, blood in the stools and the contrast between the pulse up to 120 and the normal temperature, with the intermittent character of the disturbances, were finally explained by the purpura eruption the sixteenth day.

Reduction of Subtrochanter Fracture.—Costantini and Vigot comment on the ease with which they were able to reduce and immobilize a subtrochanter fracture in three cases by placing the patient prone on a table, with an opening allowing the thigh to fall through, the heel suspended a little below the table, thus flexing the knee at a right angle This attitude brings all the parts into normal position for repair.

Vocational Reeducation of the Maimed.—Van Roy deplores the waste of time and opportunity when the maimed are allowed a convalescence furlough which usually confirms the vicious habits and contracture in the wounded, requiring weeks to undo. He declares that the professional training of the muscles should begin at the very earliest possible moment. It should be along the lines of the man's old trade when possible, or should aim to bring as many muscles as possible into play. Instead of the convalescence leave, the man should be compelled to go to work at his old trade, to a certain extent at least. If this is out of the question, he should be set to work in the fields or gardens. This would benefit him in every way, and hospitals should be planned to have fields or gardens available for the purpose. The question of rehabilitation of the maimed has numerous aspects according as the man requires vocational reeducation, functional restoration, physical reeducation, or vocational retraining if he is disqualified for his old vocation. If in addition the distinction is made between reeducating for military and for civil life, he thinks the results would be superior to those realized at present.

*Secondary Disturbances from Hysteria. G. Rousey, J. Boisseau and M. d'Oelsnitz.—p. 637.
Vitiligo and Syphilis. C. Withe and others.—p. 640.

Disturbances Secondary to Hysteria.—The paralysis and contracture in cases of hysteria have been called by some reflex nervous disturbances; others explain them by the dynamogenic theory. Roussy and his co-workers explain them by what they call the *théorie dyskinétique.* They regard the motor disturbances as of purely hysteric nature, or, as they prefer to say, pithiatic nature. All the other elements are secondary to the hysteria. In treatment, they focus their efforts to cure the hysteria by the usual psychotherapy. The immobilization of the parts to prevent their hurting, after a wound, or the vicious use of the member favors the development of the deformity in the predisposed, and the abnormal position impedes the circulation and the innervation. Passive exercise of the part is not of much use, but when the attempt is made to use the part normally, physiologic conditions begin to be restored. These hysteria patients, however, do not have the will power to attempt to use the part normally. Their frame of mind resembles that of the insured after an industrial accident. Experience with 2,000 cases of different psychoneuroses has demonstrated, they say, that this *syndrome d'utilisation vicieuse* or *syndrome dyskinétique* should be combated at the earliest possible moment. Physicians should watch out so that it should not be allowed to develop. The hysteria should be treated before these motor disturbances become a settled habit. Examination of the sound mate always reveals some predisposition on the part of vessel and nerve functioning.

*Large Doses of Camphor in Pneumonia. E. Feer.—p. 1601.
Treatment of Anemia. E. Bürgi.—p. 1604; W. Löffler.—p. 1618.

Camphor in Pneumonia.—Feer gives camphor in larger doses than others advise, and places it in the front rank in treatment of croupous and catarrhal pneumonia. It proved effectual also in the malignant pneumonia of the recent influenza epidemic in several apparently doomed cases. It is of not much use when given too timidly. One weakly boy of 6 with severe influenzal pneumonia, somnolency, cyanosis and high fever, weak pulse of 140 and 160, was given two daily subcutaneous injections of 10 c. c. of a 20 per cent. camphorated oil, and remarkable benefit followed, the albuminuria disappearing and consciousness returning. An empyema developed then which proved fatal the sixteenth day. The child had been given in eleven days 220 c. c., representing 44 gm. camphor. A delicate girl of 11 with influenzal pneumonia of left lower lobe and unilateral otitis media, with somnolency after the fifth day, was given from the sixth day on the same treatment as above. The seventh day the other lung showed infiltration; the twelfth day the whole of the first lung became infiltrated and the child seemed moribund, with tracheal râles. She recovered consciousness the fifteenth day and by the twenty-first the lungs were nearly all clear. During all this time she had been given the camphor, receiving thus 260 c.c of camphorated oil, representing 52 gm. camphor. These cases demonstrate that even children can bear large doses with advantage. For children under 6, he gives one or two injections of from 5 to 7.5 c.c of the 20 per cent. camphorated oil. He did not witness any benefit from normal serum or polyvalent pneumococcus serum, sometimes given before development of the pneumonia, but always without effect. The camphor, in large doses, on the other hand, is unable to abort the pneumonia, but it modifies conditions in the circulation so favorably that even desperate cases may be enabled to pull through. In adults he advocates injecting 10 or 15 c.c of the 20 per cent. camphorated oil twice a day or even more at need. The physician makes the injection himself at his two calls, or he might inject 20 c.c if unable to make more than one call a day. He adds that there is scarcely any danger of giving too large and injurious doses as is liable to be the case with digitalis and caffein. He has never observed any injury from the large doses of camphor or heard of any. Only Weintraud has mentioned agitation under its action, while Feer himself has found it display rather a sedative action. Harm from it in these doses could occur only when, from lack of grape sugar and oxygen in the organism, the formation of glycuronic acid, with which the camphor is harmlessly eliminated, might be hampered.

Policlinico, Rome

Nov. 15, 1918, Surgical Section No. 11

*Putrid Infection of Wounds. L. Fioravanti.—p. 321. Conclusion.
*Oblique Suture of Intestine. A. L. Soresi.—p. 340.

Putrid Infection of Wounds.—Fioravanti recalls that the gas-producing bacteria are all anaerobic, while the nongas-producing are the aerobic proteus, subtilis and colon bacilli. Gaseous phlegmons are the same by cause and nature as the gas gangrene, but the limitation of the process renders it more amenable to surgical measures. Gas may be produced by decay of tissues under the action of aerobic bacteria, but this is quite different from gas gangrene. The serum of the wounded with putrid infection never displayed any agglutinating properties for any of the germs, aerobic or anaerobic. This he ascribes to the intense agglutination induced in the tissues of the putrid wound; this prevents absorption of the antibodies which would generate the agglutinins. As the wound heals and loses its putrid character, the antibodies become absorbed and agglutinins are developed which clump the staphylococci, etc., isolated from the purulent secretions of the wound.

Oblique Entero-Anastomosis.—Soresi gives thirteen illustrations of his method of uniting the intestine which avoids the drawbacks of end-to-end and of side-to-side suture, and leaves the intestine wider at the point of suture, thus obviating any tendency to stenosis. In his preliminary report he called his technic a new method of lateral anastomosis, but he now prefers to style it oblique anastomosis, as it is not a lateral suture although it begins with this, the side-to-side suture being a mattress suture with silk 40 cm. long. The ends of the stumps are then slit lengthwise, parallel to and about 3 cm. from the seroserosa suture, stopping 3 mm. short of its ends. This leaves six raw edges, four lengthwise and two transverse, and the corner is cut off rounding. The inner raw edges are then sutured together with catgut. As there is now no corner, there is then left only one long single raw edge on each stump. These edges are sutured together, the slanting edge on one stump fitting against what was the straight transverse edge on the other. The one single suture thread does for the entire operation. The two ends of the suture thread meet in the middle, and then complete the seroserosa suture all around. The result is like an end-to-end suture, but the line of juncture is oblique. It is safer than the end-to-end, takes less time, not over five or six minutes in all, while the single suture thread used much facilitates the whole. He uses black silk, as it shows up better during the operation. One important feature of the technic is that as the stitches are taken they are drawn taut in turn, and held firm, with anatomic forceps, which also inverts the sutured edges. The segment containing this anastomosis is much wider than the normal bowel, and retains all its anatomic and physiologic relations, the natural course of the feces unmodified. His preliminary communication was summarized in The Journal March 6, 1915, p. 859. The years of experience with the method since, he reiterates, have confirmed its advantages.

*Cartilage Grafts in Reconstruction After War Wounds. G. Fantozzi. p. 505. Commenced in No. 41, p. 481.

Nov. 9, 1918, **19**, No. 45

*Acidity of the Urine. E. and E. Pittarelli.—p. 529. Commenced in No. 44, p. 517.

Cartilage Grafts.—Fantozzi declares that the results obtained in the last eight years with cartilage grafts in Ceci's surgical service at Pisa have been so gratifying that high hopes can be based on this technic reparative orthopedic surgery. Cartilage taken from the costal arch was utilized to reconstruct the tip of the nose, the septum, the ear, and correct saddle nose and other deformities, with the finest results. In none of the numerous cases was there anything approaching a failure. He describes what has been done by others in the line of cartilage grafts, and gives the details of a case in which the tip of the nose had been bitten off. The patient was a young Italian woman, the victim of an atrocity in the war between Italy and Turkey. The nose was reconstructed in 1911, and the results during the seven years since have been beyond criticism. The new nose built up with cartilage and with a skin flap from the left arm is better looking than the original nose, to judge from an old photograph.

In reconstruction work after war wounds, he advises allowing several months to elapse before attempting it, as there is danger of rousing latent infection otherwise. Massage, heliotherapy and other measures, especially hot applications, to enhance the vitality in the parts will facilitate the task of repair by softening cicatricial tissue and warding off adhesions. A preliminary course of iodids or injections of thiosinamin might prove useful in certain cases. Radiography should not be neglected, as this might reveal foreign bodies, scraps of projectiles, etc., which might compromise the outcome of the operation. He gives nearly three pages of bibliography, set solid, on cartilage grafts and reports two cases in which cartilage was used to reconstruct the face after an extensive war wound of the face. One of the men had a comminuted fracture of the zygomatic bone with loss of the entire malar bone. A plaster model of the cavity left by the loss of the malar bone was first made. Then a piece of cartilage was cut from the costal arch and modeled to copy the plaster cast. It was then fitted into the face and smalle pieces of cartilage were fitted in above to reconstruct th orbit and the projection of the zygoma. The skin was suture leaving a small glass drain for one day. A starch dressin was applied, and the region was dressed four times in week, by which time healing by primary intention wa complete.

Acidity of the Urine.—The Pittarellis report critical an experimental research in addition to their clinical analysi of 7,500 specimens of urine, which have established, the think, that the acidity of the urine is not the simple thin generally accepted. There are at least two acidities, on reacting to methyl orange, and the other to phenolphthalein It would be interesting to study the proportions betwee them in different diseases. The acidity that responds t methyl orange is not constant, like the other. There is als a latent acidity, which can be rendered evident by additio of formaldehyd. The true acidity of the urine, that is, th acidity due to the free or semicombined acids, forms scarcel two-thirds of the acidity we estimate with litmus paper, etc The other third is made up of salts of weak bases combine with weak acids. This proportion keeps quite constant. Th true acidity of the urine, therefore, is always lower tha the figures hitherto accepted as correct; it corresponds o an average to an acid solution of the strength of thirtieth-normal.

To distinguish between the real and the apparent acidit of the urine, two equal volumes of urine are treated each with several c.c. of calcium chlorid to transform all the phosphoric acid into calcium salts. Then one specimen is tinted with phenolphthalein and the other with dimethyl-amido-azobenzin, and the first is rendered neutral with tenth normal sodium hydroxid solution and the other with tenth normal hydrochloric acid solution. The alkali required for the first specimen corresponds to the sum of the free weak acids and the combined weak acids. The acid required for the second specimen corresponds to the weak bases combined with the weak acids and therefore also to these weak acids transformed into salts. The difference between the volume of the sodium hydroxid and the volume of the hydrochloric acid corresponds to the free acids.

*Bronchopulmonary Spirochetosis. A. Corvetto.—p. 141.
Psychanalysis. H. F. Delgado.—p. 148. Cont'n.

Pituitary Syndrome.—Olaechea reports a case which he says is a counterpart of one reported in 1917 by Claude and Lhermitte as a case of infundibular syndrome from a tumor in the third ventricle. Olaechea's patient was a woman of 35, previously healthy. The first symptoms were impairment of vision and reduced sensibility in the right side of the face, mucosa of the cheek, the teeth, and hyperesthesia in the right side of the tongue, with deafness and exaggerated tendon reflexes on that side. There was bilateral choked disk, and in walking she diverged constantly to the right and the head became twisted toward the right. In ten months the blindness was total and muscular contractions interfered with chewing; sometimes fluids were expelled through the nose. The temperature, respiration, circulation and the digestive and urinary apparatus seemed to be functioning normally, until toward the last intense headaches and tachycardia followed any attempt to sit up. There were also periods of narcolepsy and pronounced polyuria. The symptoms suggested leptomeningitis in patches. The cerebrospinal fluid was limpid but contained tubercle bacilli. There was evidently disturbance in pituitary functioning from compression of the infundibulum.

Ambard's Ureosecretory Constant.—Velasquez remarks that Ambard's formula cannot be used when the output of urine is less than 500 c.c. in the twenty-four hours. If the coefficient is only temporarily low, due to passive congestion from weak heart action, improving conditions in the heart functioning will raise the Ambard index. The formula cannot be depended on, he reiterates, unless the urea in the blood and in the urine and the ammonia in the urine are all determined.

History of Early Spanish Colony in Peru.—In this installment of his work "Locos de la Colonia," Valdizan describes the fools and buffoons kept by the governors of the province and others. He mentions also other persons who were or pretended to be half-witted, some of whom played a prominent part in the life of the colony.

Bronchopulmonary Spirochetosis.—Corvetto reviews the present status of what Castellani described in 1905 as bronchospirochetosis, and describes a case personally observed. The patient was a young Indian policeman and the disease was chronic with occasional acute exacerbations. The onset was with a chill and high fever for four days, but by the end of the month there was only a dry cough with serous and bloody expectoration. The microscope showed the sputum swarming with spirochetes. Under symptomatic measures they gradually disappeared from the sputum until by the end of the month only very few could be found, and the man has been in apparently complete health since. Corvetto warns that so many Asiatics are coming to Peru now that there is danger of an epidemic of this bronchopulmonary spirochetosis.

*Asthma in Children. J. G. del Diestro.—p. 577.
*Mycosis of Pharynx in Child. A. M. Calderin.—p. 596.

Asthma in Children.—Diestro reviews the features which differentiate asthma in children from the attacks of suffocation with the exudative diathesis and spasmophilia, which resemble but are not true asthma. He describes four cases of the latter in children from 8 months to 9 years old, previously apparently healthy. Two of these children were of the same family and the attacks came on at the age of 6, when the children were taken from Madrid to a northern summer resort. The mother was subject to similar attacks, and the characteristic crystals were found in the sputum of all three. The infant's dyspnea and cyanosis were extreme and a gouty taint was evident in this family. In all the children the attacks grew less severe and less frequent, and the children seemed to outgrow the tendency in from two to four years. In one of the cases true asthma coincided with enlarged tuberculous glands in the mediastinum, but the crystals confirmed the diagnosis. Infarcts in tuberculous mediastinal glands induced in some other children attacks deceptively resembling true asthma, and improving under tuberculin treatment. One of the children died of meningitis a year later. Children with the exudative diathesis may present recurring tracheobronchitis or attacks of asthma. Such children usually have noisy breathing, the mothers saying that it is the "noise of the phlegm." This is persisting, but the acute disturbances resembling asthma may alternate with skin manifestations. In one infant the eczema and the asthmatiform disturbances ebbed and waned alternately, unmodified by any measures but finally disappearing, the child as it approached the age of 5 being in apparently good health. In another infant, 4 months old, the enlarged thymus induced cyanosis and tendency to suffocation suggesting asthma. At first they occurred only when the child was crying, but later they became almost continuous. The parents would not consent to operative measures and the outcome is not known.

Actinomycosis of the Tonsil.—The usual measures applied to the acute tonsillitis in a young child failed to modify it and no benefit was derived even from gargling with glycerin containing 2 per cent. iodin and 8 per cent. potassium iodid. The absence of general symptoms and the refractory behavior suggested that the trouble was a mycosis, as there was a history of a stalk of grain being driven into this tonsil during a fall some time before. The tonsil was covered with nine white excrescences, and after failure of other measures, these excrescences were dug out, one by one, with prompt and complete return to normal.

American Medical Solidarity. Editorial.—p. 487.
*Importance of Treating Optic Neuritis Even of Long Standing. Juan Santos Fernandez.—p. 490.
*Ocular Tuberculosis. F. M. Fernandez.—p. 500.
Measles and Scarlet Fever Due to Alimentary Arsenic or Iodin Poisoning. V. de Castro.—p. 513.

Old Optic Neuritis.—Santos Fernandez insists that when blanching of the papilla is due to remote causes in brain or medulla or meninges, the optic neuritis might possibly have been arrested or cured if it had been systematically treated from the first or even at a later stage. The success we so often realize with specific treatment when syphilis is responsible for the blanching of the papilla should encourage heroic efforts in this line under other conditions. He reports five cases to sustain this view that possibly some of the nerve fibers might have escaped degeneration and might have been trained to recuperate their function. In these five cases the blanched papilla and the remnants of vision have not grown any worse during the long periods, up to forty-five years, during which the patients were under observation. In most of them the optic neuritis followed meningitis in early childhood, but the stationary character of the affection should have warned of the possibility of recuperation. The outcome cannot be deduced from the ophthalmoscope findings. The blanching of the papilla may last for weeks or years, and the vision may be impaired very little or be lost entirely. If the affection develops in the form of a central scotoma, the temporal sector of the papilla blanches first, and for a time may be the only sign of the degeneration. This occurs so often with alcohol intoxication that he called attention some years ago to this alcoholic amblyopia as a sign of alcohol poisoning. In conclusion he recalls the marvelous results now currently obtained in children completely blind from meningitis who recover vision under the influence of antimeningococcus serum.

Tuberculosis of the Eye.—Fernandez reviews the various forms in which tuberculosis can manifest itself in the eye, adding that on account of the insidious onset the tuberculous process is liable to escape recognition. The ocular process is generally secondary, but seldom secondary to pulmonary lesions. Any eye affection running a chronic course is suspicious of tuberculosis. Tuberculin treatment is the main reliance and has proved very successful in some cases, although it fails in others. It has given the best results in tuberculous iritis. Many have reported surprising cures under it, especially when associated with guaiacol applied locally in a 3 per cent. salve or 2 per cent. solution, or by subconjunctival injection. Darier has reported good results from subconjunctival injections of tuberculin in cases of tuberculous choroiditis; he explains this by the close communication between the subconjunctival space and the choroid. Others have reported good results combining this with subconjunctival injections of guaiacol.

Iodin in Therapeutics. VI. A. S. Alvarez.—p. 24.
*Prophylaxis of Valvular Lesions of the Heart. A. Simonena y Zabalegui.—p. 42. Conclusion.

Obstetric Eclampsia.—Roe relates that there were only two fatalities in the thirty-two cases of eclampsia in which he gave morphin by Rouvier's technic. The first dose is 0.02 gm., with half this dose again in half an hour and again in another half hour, continuing with 0.01 gm. at hour intervals thereafter. The bowels are rinsed out with 6 or 8 liters of boiled water every eight hours. If the morphin could have been begun at the very first convulsions, he is confident that all the patients might have been saved. Thirteen cases are reported in detail.

Roentgen Periscope.—With Bois' periscope the roentgenologist can stand entirely outside of the field of the rays while inspecting the shadow on the screen, as he shows in an illustration. The periscope can be used in broad daylight.

Ambard's Ureosecretory Constant.—Zapata warns that the dread of having blood drawn or other cause for emotional stress may affect the diuresis to such an extent as to modify the Ambard coefficient when urine is obtained for the purpose. He makes a point of getting the urine for the test before drawing blood or other maneuver, and strives to keep the patient tranquil and placid with every biologic test.

Prophylaxis of Valvular Disease.—This long article, which has been continued serially during two months, reviews the present status of prophylaxis of disease of the heart orifices and valves. The main point is thorough treatment of acute rheumatism and syphilis until they are cured or become extinct. Next in importance is the early and active treatment of every infection, and, last but not least, moderation in eating and drinking. Also active muscular exercise during the years when life is taken more easily and one is inclined to lapse into settled sedentary habits in the thirties. Modern life strains the mental faculties but lets muscles rust from disuse, and this tendency favors heart disease.

*Fibrous Transformation of Adipose Tissue in Knee. A. M. Angel.—p. 241.
Dislocations and Fractures of Elbow. S. G. Hurtado.—p. 261. Cont'n.
Present Status of Chronic Myocarditis. A. Mut.—p. 265.

Chronic Inflammation in the Knee.—Angel has not been able to find any record of the affection in question. Without any new cause there seems to be an attack of mild inflammation in one or both knees; there is an effusion of synovial fluid but not much pain and no fever. The bones are shown by radioscopy to be entirely normal, and these patients seldom have any history suggesting gonorrhea, gout, tuberculosis or rheumatism. The trouble is a chronic inflammation of the adipose ligament with occasional transient involvement of the serosa of the knee joint. The cells of the adipose tissue have become transformed into fibrous tissue under the influence of some repeated slight trauma, such as the rubbing of the knee against the bedstead in doing massage, or a sudden wrench as in playing football. When the fibrous transformation is once realized, nothing but removal of the adipose ligament will cure the condition. He describes briefly the technic with which he has removed the adipose ligament without opening up the joint or injuring the serous membrane.

*Antisepsis for Surgery of the Eyes. R. Guiral.—p. 645.
Inaugural Address of Physiology Course. R. P. Vento.—p. 649.

Modern Antisepsis in Surgery of the Eye.—Guiral had to abandon tincture of iodin in surgery of the eye as the iodin toughened the conjunctiva until it was like parchment, too hard to cut readily. Otherwise the iodin was extremely satisfactory. He is now using a mixture of 0.5 gm. each of crystal violet and verde violet in 50 gm. each of distilled water and 80 degrees alcohol. This is applied freely to the eye after the cocain; in a few minutes he rinses out any excess of the stain. If the eyeball is very intensely stained, he anoints it a little, and the operation can proceed with all confidence that the tissues are perfectly sterilized. His success in a series of 100 cataract operations amply proves this.

*Ophthalmoplegia of Malarial Origin. J. C. M. Fournier.—p. 626.

Transfusion of Citrated Blood.—Agote describes his first application of the citrated method for blood transfusion, Nov. 9, 1914, and the history of the general adoption of the method since.

Aplasia of Spine and Ribs.—Butler gives roentgenograms of a young man apparently healthy until an attack of kidney colic. The roentgen rays then disclosed that half of the third lumbar vertebra was missing and also nearly all of the left lower rib. Both deformities can be explained by assuming an intra-uterine lateral inflexion of the spine.

Splenectomy.—Mérola advises utilizing, more than has hitherto been the case, the natural planes of cleavage in the abdomen in surgery of the stomach, etc. He describes the inframesocolic and the supramesocolic planes of cleavage. For resection of a segment of the stomach, its cleavage connection with the spleen and pancreas has to be broken up as otherwise they are pulled unnecessarily out of place when the stomach is lifted up. On the other hand, this cleavage facilitates removal of these organs together, as he shows in reporting a case of a large tumor in the spleen requiring resection of the tail of the pancreas. The whole mass of the spleen, etc., was removed in one block after ligation of the splenic artery, which before separating the ligaments had been inaccessibly buried. In a second case the spleen, a large segment of the stomach, and the tail of the pancreas were removed together as one mass, thanks to the retrogastric-pancreatic plane of cleavage. The operation was complicated, however, by resection of the left angle of the colon, the necessity for which had not been anticipated, and the patient succumbed two days later. His incision for these operations is on the median line. If conditions are found which justify the extirpation, he continues the incision upward and to the left, and resects 2 cm. of the bony end of the seventh rib. If the pleura is opened, he sutures it at each of the lips of the incision to isolate its cavity. This gives ample access to the region and opportunity for taking advantage of the retrogastric-pancreatic plane of cleavage, "one of the wonderful cleavages which make such operations in the upper abdomen possible."

Nephropexy Through the Peritoneum.—Mérola has noticed that when there is a floating kidney, the right angle of the colon is generally sagging also. When there is congenital displacement of the kidney, the cecum and the colonic angle are often abnormally low. In one case of movable kidney the colonic angle had sagged into the iliac fossa. In operating for appendicitis in this case, after removing the appendix he incised the peritoneum, thus reaching the movable kidney. He fastened it to the anterior aponeurosis of the transverse muscle and to the peritoneum. Then the peritoneum was sutured and the colonic angle was lifted up with a few supporting stitches, thus bringing it up until it concealed the suture in the peritoneum. The nephropexy was thus done without a special incision for it, utilizing the appendicectomy incision. The same might be done, he adds, at a gallstone operation. He does not approve of fastening the kidney to a rib. Still another method of nephropexy consists in suturing the peritoneum to the wall below the kidney so that the latter cannot slip down, once replaced in its position. Two U stitches with silk hold the peritoneum against the muscular wall. The ends can be tied just below the skin, through a small incision at the back. The suture threads thus hold the peritoneum against the wall and hold back the kidney in its place.

Total Ophthalmoplegia of Malarial Origin.—Fournier reports a case of this kind and states that he can find no duplicate of total malarial bilateral ophthalmoplegia in medical literature. The ophthalmoplegia was purely motor and yielded promptly to quinin treatment. The onset was sudden, accompanied by severe headache and chill. The man was an Italian sailor of 29. The ophthalmoplegia was total in both eyes and left facial paralysis had developed with it and subsided at the same time. In a recent compilation of twenty-five cases of malarial polyneuritis, in only two were cranial nerves involved, and these were the seventh pair.

*Sugar Injections in Whooping Cough. A. J. Armando and L. V. Berisso.—p. 287. Concluded in No. 11, p. 325.

Sugar Treatment of Whooping Cough.—Armando and Berisso report treatment by intramuscular injections of 5 or 10 c.c. of a 100 per cent. solution of saccharose in twenty cases of whooping cough. The first effect noted was that the nights passed without paroxysms; the number during the day increased at first, but then grew progressively milder and shorter and in ten or fifteen days the cough had disappeared. There was no expectoration after the eighth or tenth day. There were no complications or by-effects. No other medicine was given. The disease was of from ten to twenty days' duration in the twenty cases; the details of all are given in full.

Cultivation of Medicinal Plants in Argentina.—Dominguez is director of the Institute of Botany and Pharmacology of the University of Buenos Aires, and he here replies to an inquiry from the government in regard to the feasibility of cultivating the cinchona in Argentina. He specifies certain regions where conditions would be favorable, and advises starting with the *C. succirubra* as the hardiest species. If this succeeds, then others could be tried. Near the equator a high altitude is desirable. In Java the official plantations are at 1,230 to 2,350 meters but some private plantations are as low as 550 meters. All known plantations are above this altitude except in Australia where, although at an altitude of only 33 meters, the bark has yielded 6.50 per cent. of alkaloids. The *C. calisaya* seems to do best at an altitude of 2,000 meters. With higher altitudes the levorotatory alkaloids seem to increase while the proportion of dextrorotatory decreases. The cinchona plants can bear a temperature of 2 C. but at freezing point or below they are seriously injured, as also with very high temperatures. The admissible range is from 4 to 33 C. that is, a minimal average of 15 and a maximal average of 27 C. The rainfall has to be at least 1.200 mm.; in the Java plantations the annual precipitation is 2,300 to 4,500 mm. with a maximal humidity of 96 per cent. There is no yield the first four years.

Tuberculosis and Moving Picture Shows.—Ivanissevich remarks that the moving picture shows "with which the entire republic is plagued," are in halls which are kept closed against the sun and air and are never disinfected. They are actual hotbeds for germs of all kinds, and cannot fail to be a potent means for transmission of tuberculosis. Five guinea-pigs were smuggled clandestinely on three occasions into a moving picture hall for a few hours and two of them died of tuberculosis the thirtieth and fiftieth days. Further experiments were not allowed. He pleads that the halls should be opened to the sun and air for at least six hours every day, and exhaust ventilation be provided at all times. The laughter at the comic shows helps to scatter germs. A hall holding 300 shelters 9,000 in a month and 54,000 in six months. As 4 per cent. of the populace are estimated to be tuberculous, this would average 2,160 tuberculous visitors to the hall during the six months, and the bacilli expelled in coughing and speaking find unparalleled conditions for proliferation in these dark and unventilated halls.

*Artificial Production of Sarcoma in Rats. N. Umehara.—p. 43. Conc'n.
Curative Action of Radium on Hen Sarcoma. H. Ogata.—p. 49.
Leukocyte Count in Sarcoma Rats. T. Maeda.—p. 50.

Sarcoma Produced from Transplanted Adenofibroma in Rats.—The first part of Umehara's article was reviewed in these columns, Jan. 25, 1919, as he told of transplanting a spontaneous benign tumor found on a white rat through numerous generations of rats. He finally succeeded in modifying the tumor grafts by injecting sudan III in olive oil directly into the tumor, as it developed from transplantation in the eleventh generation. No other substances tested induced malignant transformation, and this occurred only in two of the three rats thus treated. The sudan oil was injected, a drop at a time, at five or six day intervals, repeated seventeen times in two rats, which then died, the forty-second day and the fifty-seventh day. A third rat died after the eighth injection, without the tumor showing any modification. The inoculation tumor at the time the injections were commenced was about the size of the head of the thumb. It grew to be as large as a goose egg, and the microscope revealed that part of it was a sarcoma, of a polymorphous type, which seemed to have developed in consequence of the chemical irritation from the sudan oil. Transplantation further of the sarcomatous portion of the tumor elicited sarcomatous growths in other rats, while transplantation of the nonsarcomatous portion of the tumor caused the production only of fibromatous tumors of the same benign type as at the beginning of the series. The malignant inoculation tumors were macroscopically soft and of a very rapid growth, with early necrosis and softening and numerous metastases in lymph glands, etc., so that the animals succumbed to cachexia. Both spindle cells and round cells were evident. The transplantability of the original tumor had begun to wane by the later generations but, after this malignant transformation, it revived again so that he was able to transplant this artificial sarcoma through fourteen generations, with from 45 to 90 per cent. positive results, a total of positive results in 291 of the 445 rats used in the experiments. The microscopic and biologic findings were very much like those observed in the human. The phenomena reported confirm Virchow's irritation theory of the origin of cancer, and also Yamagiwa's dictum that the influence of the medium is what forms the cancer cell. The sarcomatous tumors finally displayed a tendency to return to a fibromatous type of tumor. There is no doubt in Umehara's mind that this artificial rat sarcoma developed from the connective tissue elements of the adenofibroma. The article is illustrated, with a full summary in German and considerable bibliography.

Comparison of Recent Epidemics of Influenza. A. Giltay.—p. 1678.
The Point of Lessened Resistance. A. Welcker.—p. 1679.

Reform in Medical Education.—Van Rijnberk quotes R. M. Pearce's three articles in "Medical Research and Education," published in 1913, and comments on the similarity between *his* ideas and those of Schwalbe (mentioned recently, page 317). Pearce's motto is also "Do it yourself," and he advocates that the hours devoted to lectures and laboratory work should be in the proportion of one to six or eight. At Amsterdam, Rijnberk adds, the proportion is about one to one. He cites further that "science lives in the laboratories and clinics. When it is dead, it is buried in a book." In conclusion Rijnberk remarks that many of his readers will regard Pearce's ideas as "all too American." Especially his denunciation of too much oral teaching. But in the Netherlands the tendency is too much in the other direction. In Germany, the methods of examining for a degree have not been changed at all for seventeen years, and in the Netherlands not for half a century.

Operative Treatment of Chronic Pulmonary Tuberculosis.—Hannema reports in detail the case of a married woman of 32 who had presented symptoms of pulmonary tuberculosis for about eight years. The right lung seemed to be entirely involved, while the left lung seemed to be clinically sound. The heart shadow was lost in the shadow cast by the right lung, and there was daily considerable blood in the profuse expectoration while the woman was growing weaker, although there was not much fever. A large cavity was evident and the conditions precluded artificial pneumothorax. A thoracoplastic operation, according to Wilms' technic, was done as the lung displayed a tendency to shrivel, and all that kept it from collapsing was the skeleton. From 4.5 to 6.5 cm. were resected from each of the nine ribs, beginning at the lowest. The pleural cavity was not opened but the right side of the chest sank in at once. Healing was delayed by the cough and expectoration, and the pulse was weak and fast, but the appetite was good. Twenty-three days later the ribs were resected from the rear, the cartilage and a small part of the second to the sixth ribs, inclusive, under local anesthesia. The muscles were sutured with catgut, the skin with pure silk. The blood disappeared from the sputum after the first operation, and the general condition rapidly improved. The intervention unmistakably saved the woman's life. She now, fifteen months later, feels well but takes care of herself and there is still a little sputum. After repeated examinations, a few tubercle bacilli were found, showing that the woman has not been completely cured, but everything seems to promise this in the end, as the patient is cooperating with zeal and intelligence. In a recent compilation of 41 similar operative cases, 8 were cured, 7 much improved and 13 improved; in 3 the condition has remained stationary; in 4 it has become aggravated, and 6 have died. Hannema gives the minute details of his case, with the roentgen findings, and classes it in the group of the much improved.

Ugeskrift for Læger, Copenhagen

Nov. 21, 1918, **80**, No. 47

*Phototherapy of Surgical Tuberculosis. E. Collin.—p. 1841.
*Technic for Lumbar Puncture. B. Pontoppidan.—p. 1855.
*Wassermann Reaction. H. I. Schou.—p. 1858.

Light in Treatment of Tuberculosis of Bones and Joints.—Collin declares that rational phototherapy is still in its infancy, notwithstanding the great advances made in recent years under the leadership of Finsen, Rollier and Reyn and Ernst. The two latter in the last five years have demonstrated that the light treatment alone, without the cooperation of climatic influences, cured as effectually at the Finsen Institute at Copenhagen as Rollier's mountain climate sunbaths. They proved that artificial light can take the place of sunlight from the therapeutic standpoint. The arc light rays seem to be more potent than any other source of radiant energy, although some prefer the quartz mercury vapor light. As the latter is less expensive to install, the two seashore sanatoriums for tuberculous children in Denmark are equipped with this, and Collin here reviews the experiences with 138 tuberculous children given this treatment after they had failed to show improvement under the general measures alone. They were thus the severer cases; in 102, general light baths were given, in 52 merely local, and in 34 regional baths, in some associated. The average length of the course of light treatment was five months; the range was from six weeks to ten months. All this material is described in detail, with the technic shown in illustrations and the outcome.

Recent reexamination shows that there has been recurrence in 13 of the 138 cases; in 11 of these 13 cases the course of phototherapy had been less than two months. Evidently the treatment was arrested before it had answered its complete purpose. In the remaining 2 cases, the children had other tuberculous lesions besides those that had been treated. The results in the total 138 cases must be regarded as extremely favorable. The seashore environment may have contributed, but as this alone had shown no benefit beforehand, it need not be taken much into account in estimating the outcome. The relatively rapid cure, the absence of disfigurement and the good functioning of the limbs are special advantages of this phototherapy. The experiences related impress the wisdom of sending children with tuberculous processes in glands, bones or joints to a seashore sanatorium and supplementing the ordinary measures with courses of light treatment, sunlight, arc light or quartz lamp.

In 108 cases the tuberculous lesions seem to be cured; in 20 there was great improvement, and in 12 others some improvement. No benefit was observed in 16 cases and the lesion progressed in 4; these were cases of spondylitis or white swelling of the knee. All of the gland cases and tendon sheath cases and cold abscesses were improved or cured. The children were between 4 and 15. In one case ichthyosis subsided under the light treatment applied for a tuberculous process. The children sometimes developed fever under the exposures, and recurring febrile bronchitis was not infrequent. The latter may have been the result of chilling during the exposures—the quartz lamp does not generate much heat—or it may have been from activation of latent tuberculous peribronchitis. There was complicating pulmonary tuberculosis in 6 cases, and in 4 the exposures had to be suspended as the condition was aggravated by them. This group includes the two spondylitis cases. Keratoconjunctivitis developed in 12 cases, and he queries whether this was due to injury of the eyes from the light, or activation of a latent process, or the result of the universal reaction to the toxins. The latter seems to him the most plausible explanation. An epidemic of varicella in the sanatorium did not spare the exposed children, and the pustules seemed to be extra large in them, resembling actual variola. Erysipelas developed in 5 cases, apparently uninfluenced by the phototherapy.

Technic for Lumbar Puncture.—Pontoppidan reports that lumbar puncture in a recent series of 100 cases was done alternately with the patient seated and reclining. Only 2.5 c.c fluid were withdrawn, and none of the patients had any serious disturbances afterward. In 58 per cent. there was not a trace of headache or pain in the spine or other by-effects. This group included 35 seated and 23 reclining patients. In the others, presenting some by-effects, for from one to five days, the proportions between the seated and the reclining were about equal. In 6 cases the by-effects were perceptible for from six to ten days in seated patients, and from six to eighteen days in 4 given the lumbar puncture when reclining. These experiences show that the reclining posture has no advantage over the seated. They demonstrate further that it is not necessary to have the subject go to bed afterward. This was always advised, but the advice was seldom followed by out-patients. In short, Pontoppidan advocates doing lumbar puncture even in the office or dispensary when it is not convenient for the patient to enter the hospital.

Serodiagnosis of Syphilis.—Schou says that no Wassermann reaction was obtained in 1,457 of 1,654 persons tested, but it was positive in 136 who had other signs of syphilis; also in 33 (2.2 per cent.) who had no other manifestations of the disease. In 28 cases with other signs of syphilis the reaction was negative, but 19 of these had been taking treatment. In the other 9 no treatment had been given, and they presented unmistakable symptoms of syphilis, either dementia paralytica, tabes, or a syphilitic brain or muscle disease. In some of these cases the spinal fluid was highly pathologic—in some cases giving a positive Wassermann, but there was no seroreaction to be elicited in the blood.

TYPHOID FEVER OCCURRING AFTER PROPHYLACTIC INOCULATION *

CLAUDE P. BROWN, M.D. (PHILADELPHIA)
Major, M. C., U. S. Army; Chief of Laboratory Service
FRANCIS W. PALFREY, M.D. (BOSTON)
Major, M. C., U. S. Army; Chief of Medical Service
AND
LEONARD HART, M.D. (MERIDIAN, MISS.)
Captain, M. C., U. S. Army
CAMP GREENE, CHARLOTTE, N. C.

Typhoid fever of recent years in our army has been conspicuous by its rarity. It is our purpose here, however, to show that while rare it cannot be considered as nonexistent; that in cases of continued fever it is still to be suspected, and, even more important, that the protection of prophylactic inoculations, great as has been their service, cannot be taken as absolute to such an extent that sanitary precautions can be neglected.

Vaccination against typhoid fever is now practiced as a routine in all modern armies. At the Fifteenth International Congress in 1912, Russell[1] summarized the statistics up to that time with reference to the use of typhoid vaccine in our army and the armies of Europe. During the same meetings Nichols[2] described some of the methods of producing typhoid vaccine, giving in detail practically the same method as is now used in producing all typhoid vaccines; and as the U. S. Public Health Service has adopted a standard for all commercial vaccine, the question of uniformity would seem to be fairly well established. Experience of the armies in the present war has continued to support the belief that such vaccination, especially since the addition of *B. paratyphosus* A and B,[3] has rendered typhoid fever, formerly a prominent war disease, a very minor source of sickness. While it is true that sanitation has been greatly improved, it is impossible to contend that it has reached such a degree of perfection as to account for this result, so that it is generally conceded that the *principal* factor has been vaccination.

Yet in spite of sanitary precautions and vaccination, occasional cases of typhoid fever, like those herein reported, have occurred. Bradbury[4] has reported four cases, and others, in addition to those studied by us, have been included in army reports of contagious diseases.

In the latter part of June, 1918, cases began to appear at the base hospital at Camp Greene, N. C., which from their gradual onsets, climbing temperatures, without evidence of local inflammatory disease, enlarged spleens, rose spots and leukopenia presented the clinical picture of typhoid fever. Cultures from blood, stools and urine resulted in isolation of the typhoid bacillus. The subsequent course of the group of cases added confirmation of the diagnosis of typhoid, by protracted fever, falling by lysis, a tendency to delirium, in three cases relapse, and in three cases small intestinal hemorrhages. It was beyond dispute, therefore, that we were dealing with a miniature epidemic of typhoid fever.

The cases belonging to this epidemic, with certain other cases occurring at the hospital, are reported in brief herewith.

REPORT OF CASES

CASE 1.—L. K., sergeant, Co. 6, 4th M. M. S. C., who came to Camp Greene, March 29, 1918, was taken sick, about June 26, with abdominal pain, headache and fever, and was admitted to the hospital, June 28. He had fever, rose spots and an enlarged spleen; his condition was febrile, including a relapse, until August 12. There were hemorrhages. *B. typhosus* was isolated from the blood and the urine. He had been a member of 8th Company until about two weeks before he was taken ill. His drinking water had been taken from an 8th Company barrel. The patient had been on kitchen police duty for a day about two weeks before. He did not drink water from any well or spring. He drank milk, bought at canteen, the bottles of milk being iced. He ate ice cream at a canteen and also at Charlotte, N. C. He had some meals at a restaurant at Charlotte. He always ate cooked foods, and had eaten no lettuce or tomatoes or other fresh vegetables. He had visited the Charlotte soldiers' club a number of times, but no private homes. The first and second typhoid inoculations had been given at Jefferson Barracks, the third at Camp Grant, between Dec. 15, 1917, and Jan. 2, 1918.

CASE 2.—A. J., private, 8th Company, 4th M. M. S. C., had been taken ill about June 22, 1918, and was admitted to the hospital, June 28, with abdominal pain, vomiting, headache, fever, rose spots and enlarged spleen. He was febrile until July 18. *B. typhosus* was isolated from the blood. His drinking water had been in a barrel. He did not drink water from any well or spring. He did not drink milk. He ate ice cream from a canteen and at different places in Charlotte. He had some meals at Charlotte, but all the food was cooked. He ate lettuce once at mess. He had been on kitchen police duty about three weeks before. He visited the soldiers' club a few times. He did not visit any private homes or the Y. M. C. A. The service record disclosed that typhoid inoculations had been performed at Kelly Field, about Jan. 1 to Jan. 18, 1918, and completed January 16.

CASE 3.—K. E. T., private, 1st Company, 4th M. M. S. C., had been taken ill about June 26, 1918, and was admitted to the hospital, June 28, with headache, poor appetite, nausea and fever; enlargement of the spleen was doubtful; there were no rose spots; he was febrile until July 17; a recrudescence occurred, July 24 and 25. *B. typhosus* was isolated from the blood. He had been a member of 8th Company until about two weeks before. His drinking water had been in a barrel taken from 8th Company. He usually drank from a cup hanging from the barrel. He also drank at several places in Charlotte. He never drank milk. He ate ice cream from a canteen. He had some meals at Charlotte, but always ate cooked food. He did not eat lettuce, tomatoes or other vegetables. He had been on kitchen police duty about a month before. He did not drink water from any well or spring. He visited the soldiers' club once or twice a week and drank orange juice while there, common drinking glasses being used. Ice was placed in the orange juice to cool it. The service record, Dec. 28, 1917, disclosed that typhoid inoculations had been given at Jefferson Barracks between Dec. 14, 1917, and Jan. 3, 1918.

Case 4.—R. E. G., private, medical department, base hospital, Camp Greene, N. C., had enlisted at Fort Douglas, Utah, June 4, 1917, and had served at the post hospital, Fort Russell, Cheyenne, Wyo., from June, 1917, to Jan. 3, 1918; in the medical department, 4th M. M. S. C., Camp Hancock, from Jan. 19 to April 10, 1918, and the medical department, base hospital, Camp Greene, from May 26, 1918. He had been taken ill, June 17, and was admitted to the hospital the same day with abdominal discomfort, vertigo, vomiting, sore throat, fever and an enlarged spleen. There were no rose spots. His condition was febrile, including a relapse, until July 19. *B. typhosus* was isolated from the urine. He drank water from a spigot while in the medical department of the 4th M. M. S. C. He drank water from a well at a farmhouse back of the barracks, at the base hospital. He did not drink milk. He ate ice cream at several places while in Charlotte. He did not eat lettuce, tomatoes or other uncooked food. He was not an attendant in any ward. He did not attend any one while attached to the base hospital. He did not visit Charlotte. He was not on furlough. Inoculations had been given at Fort Russell in July, 1917; he had taken six consecutive doses.

Case 5.—H. S., private, Co. 7, Casual Camp 1, had enlisted at Atlanta, Ga., June 6, 1917. From June 15, 1917, to April, 1918, he had been a member of Company C, 47th Infantry, stationed at Syracuse, N. Y., until October, 1917, when it proceeded to Camp Greene, N. C. The patient had been transferred to Casual Camp 1, and had been taken ill, July 5, 1918, and was admitted to the hospital, July 5, with headache, constipation and fever. There were rose spots; the spleen was not felt; the patient was febrile until July 20. *B. typhosus* was isolated from the urine and feces. The patient drank water from a Lister bag. He drinks milk, but had not drunk any since April. He ate ice cream at mess in Casual Camp 1 and also at Charlotte. He did not eat tomatoes, lettuce or other uncooked food. He did not visit in Charlotte. He was on furlough to Baxley, Ga., in January, 1918. Typhoid inoculations had been given at Syracuse, N. Y., in August and September, 1917. He had had two inoculations at Augusta in June, 1917.

Case 6.—K. L., private, 18th Company, 5th M. M. S. C., enlisted at Bridgeport, Conn., Dec. 13, 1917, and was sent to Camp Dix and then to Camp Hancock, Ga. He remained in quarantine fourteen days to see if measles would break out. Four days later he was sent to Camp Greene, N. C., arriving, March 25, 1918. He had been taken ill, March 11, and was admitted to the hospital, April 1, with headache, chills, weakness, poor appetite and fever. There were rose spots and an enlarged spleen. His condition was febrile, including a relapse, until April 30. The fever was undetermined, April 12. June 10, there was acute cholecystitis, for which cholecystotomy was performed. *B. typhosus* was isolated from the gallbladder. The patient had been in the kitchen one week before coming to Camp Greene. He was ill most of the time between his arrival at Camp Greene and coming to the base hospital. He drank water from a spigot at Augusta and Camp Greene. Typhoid inoculations had been given during the month of January, 1918.

Case 7.—M. K., medical department, 4th M. M. S. C., had been taken ill, June 21, 1918, and was admitted to the hospital, June 25, with headache, nausea, poor appetite and fever. There were rose spots and an enlarged spleen. He was febrile until July 9; he became a chronic carrier. *B. typhosus* was isolated from the feces, August 12. The patient messed with 5th Company. He did not drink water from a well or spring. He did not drink milk. He had had dinner in Charlotte about a month before. He did not have uncooked vegetables, milk or ice cream. He ate ice cream at Liberty Park. He did not handle any food. Water in the mess hall was taken from a galvanized iron can. A Lister bag hung outside of the 5th Company's quarters for men to use. Typhoid inoculations had been given at Spokane and Fort Russell during June and July, 1917. Repeated examinations of the urine and feces have proved that this patient has developed into a carrier.

Case 8.—C. W. T., private, 3d Company, 4th M. M. S. C., first stationed at Camp Devens about March 29, 1918, came to Camp Greene about April 26, 1918, and was transferred to 3d Company, 4th M. M. S. C. He was taken ill, June 30, 1918, and admitted to the hospital July 7, 1918, with headache, poor appetite and fever. There were rose spots and an enlarged spleen. The patient was febrile until July 26, 1918. *B. Typhosus* was isolated from the blood. The patient had had one drink of water from a pump located near the Casual Company. He drank water from a galvanized iron can in the mess hall of the 3d M. M. He drank water at the Knights of Columbus and the Y. M. C. A. He drank orange punch at the soldiers' club, Charlotte. He ate ice cream at mess, also at soldiers' club. He did not drink milk. Typhoid inoculations had been given at Camp Devens, and were completed, April 15, 1918.

Case 9.—R. H. L., corporal, 16th Company, 4th M. M. S. C., had enlisted at Greenfield, Dec. 12, 1917, and was sent to Fort Slocum immediately. He had been there four days, when he was sent to Kelly Field, where he remained one month. He was at Camp Hancock about two months. He came to Camp Greene about April 1, 1918, and was at the 9th Casual Company about one month. He was transferred to 8th Company, 4th M. M. S. C., and had been transferred to 16th Company, 4th M. M. S. C., about six weeks before. He was taken ill about July 4, 1918, and was admitted to the hospital, July 7, with headache, vomiting, constipation and fever. There were rose spots and an enlarged spleen. He was febrile until July 25. *B. typhosus* was isolated from the blood. He drank water from a barrel in the mess hall of 8th Company. He drank orange punch at the soldiers' club two or three times. He ate ice cream in drug stores in Charlotte, and at the mess of 16th Company. He ate tomatoes at the mess of the 16th Company. He ate lettuce a few times. He did not drink milk. He had no water from wells or springs. The first dose of typhoid vaccine had been given at Fort Slocum. Afterward, he had four doses at Kelly Field. Inoculations were completed the first week in January, 1918.

Case 10.—J. A. P., private, 8th Company, 4th M. M. S. C., enlisted at Fort Logan, Dec. 13, 1917. He was there two or three weeks and sent to Kelly Field. He was sent to Camp Hancock about Jan. 15, 1918. He was ill on arrival at Camp Hancock. He arrived at Camp Greene about the middle of May. He was taken ill, July 4, and admitted to the hospital. July 7, with headache, nausea, constipation and fever. There were rose spots and an enlarged spleen. He was febrile until August. There was hemorrhage. *B. typhosus* was isolated from the blood. He drank water from a barrel in the mess hall, and also a few times from wells and springs. He ate ice cream in Charlotte three or four times. He did not drink milk. He ate lettuce once or twice. He visited the Y. M. C. A. a few times. He did not visit the soldiers' club. Typhoid inoculations had been given at Kelly Field. They were completed the first week in January, 1918.

Case 11.—T. C. M., private, 7th Company, 4th M. M. S. C., was admitted two weeks before the other patients. He had been inducted into service at Union County, Miss., Sept. 27, 1918; sent to Camp Pike, Ark., and assigned to the 334th M. G. Battalion, transferred about Nov. 12, 1917, to the 150th

Infantry, Camp Beauregard, La.; transferred, Jan. 29, 1918, to the 1237th Casual Company, 4th M. M. S. C., Camp Hancock, Ga.; transferred, March, 1918, to the 9th Casual Company, 4th M. M. S. C., Camp Greene; transferred, April, 1918, to the 8th Company, 4th M. M. S. C., and transferred about June 5, 1918, to the 7th Company, 4th M. M. S. C. Two days after admission, tertian malaria was found. Urine and feces were sent to the laboratory at frequent intervals, and sometimes every day; all examinations were negative. Typhoid fever was never proved bacteriologically. The patient was admitted to the hospital, June 17, 1918. July 4, he had headache, vomiting and a rising temperature. There were questionable rose spots, and the spleen was palpable. The patient was febrile until July 22. He drank water from spigot in the 7th Company, and also from a Lister bag in the 8th Company. He drank no water from wells or springs. He did not use a common drinking cup. He ate ice cream at the mess of the 7th Company. He did not eat lettuce, tomatoes, cucumbers or other uncooked food. There had not been much illness or bowel complaint in the company. He did not visit Charlotte. He was not on furlough. Typhoid inoculations had been received at Camp Pike, Oct. 1, 11 and 19, 1917.

Case 12.—F. D. B., private, Co. M., 39th Infantry, enlisted, Sept. 1, 1917, and had been in the base hospital since Dec. 8, 1917, with pneumonia, empyema, etc. Onset of headache, vomiting, and looseness of bowels occurred, Aug. 5, 1918; there were fever and rose spots; the patient was febrile until August 30; there was hemorrhage. *B. typhosus* was isolated from the blood. The patient had been on a regular diet for some time. He had received three typhoid inoculations, at weekly intervals, at Syracuse, N. Y., in September, 1917.

Cases occurring about this period in men who had received either no vaccine or in whom the inoculations had not been completed are herewith included:

Case 13.—J. W., recruit, Co. 1, Recruit Camp 1, inducted into service, July 29, 1918, and lived at Norfolk, Va., about eleven months, returned to his home, Statesville, N. C., about one week before coming to Camp Greene, N. C. While at Norfolk, Va., he lived in a car provided for workmen by the Norfolk & Southern Railroad in their railroad yards. He drank water from a spigot, and ice water, from a bucket. He worked as a fireman and cleaner. He was admitted to the hospital, August 7. He had been taken ill about August 1. He had chill, headache, pain in abdomen, and fever. There were no rose spots nor enlarged spleen; he was febrile until September 4. *B. typhosus* was isolated from the blood. He usually ate ice cream on Sunday. He ate mostly cooked food. He drank milk every day. He did not know of any typhoid at Statesville, N. C. He had received the first dose of typhoid vaccine, Aug. 2, 1918.

Case 14.—W. W., recruit, 9th Company, Recruit Camp 1, came to Camp Greene, N. C., Aug. 1, 1918. He had been working in the steel mills at Homestead, Pa., for about eleven months. He was at his home at Weldon, N. C., one night before coming to Camp Greene. He was ill when he left Homestead, Pa. He was admitted to the hospital, August 5. *B. typhosus* was isolated from the blood. He drank water from a spigot. He used his own drinking cup. He ate all cooked food. He did not eat ice cream. He did not have typhoid inoculations or vaccination.

Case 15.—A. C., recruit, Company 10, Recruit Camp 3, entered the service about Aug. 21, 1918. He visited his mother at Lagrange, Tenn., about three weeks before coming to Camp Greene. He drank water from a well. He was ill when he arrived at Camp Greene, and was admitted to the base hospital, August 26, with headache, backache and weakness; he was febrile until September 30; a relapse occurred, October 7 to 17. *B. typhosus* was isolated from the blood. He does not drink milk. He drank water from a spigot. He received one dose of typhoid vaccine.

Case 16.—N. M., recruit, Company 21, Recruit Camp 4, entered the service about Sept. 1, 1918. His home was at Cleveland, where there had been a number of cases of typhoid. He was ill on arriving at Camp Greene, and was admitted to the hospital, September 8, with malaise, weakness and fever. There were rose spots and an enlarged spleen; he was febrile until September 28. *B. typhosus* was isolated from the blood. He does not drink milk. He drank water from a spigot. There had been no typhoid prophylaxis.

Case 17.—C. A., recruit, Company 9, Recruit Camp 1, entered the service from Hoskins, N. C., July 29, 1918. He was taken ill, September 7, with headache and vomiting, and was admitted to the hospital, September 12, with fever and enlarged spleen. The febrile condition, including a period of relapse, lasted until October 9. *B. typhosus* was isolated from the blood. He drank milk at home, where he owned a cow. He drank milk at the canteen. He ate ice cream cones from a store near his quarters. There were some flies in the mess hall. The drinking water was in a barrel, and there was ice in the water. The cup used for drinking purposes hung at the side of the barrel. The patient used his own cup to drink from. He drank water from a deep well at home. He had fresh vegetables, raised at home, on a farm. He had fresh tomatoes at mess. He received two doses of typhoid vaccine.

Case 18.—L. McD., recruit, Co. 1, Recruit Camp 4, entered the service, Sept. 4, 1918, at Spartanburg, S. C. He was taken ill, Sept. 10, 1918, with headache, and was admitted to the hospital, September 21, with fever, rose spots, and an enlarged spleen. He was febrile until October 31. *B. typhosus* was isolated from the blood. He drank water from a hydrant, except at meals, and ice water was given by the man who dipped it from the tub. He had a deep well at home. He drank no milk. He ate no fresh vegetables. He ate no ice cream. There were no flies in the mess hall. There was no history of typhoid fever at home. He received two doses of typhoid vaccine, Sept. 9 and 16.

PRECAUTIONS TAKEN

Suggestions made to the regimental surgeon of the Fourth M. M. S. C., with reference to examination of carriers, quarantine, etc., resulted in an order being issued by him to this effect:

1. Cases have been admitted to the base hospital, of recent date, that were suspicious of typhoid fever. In view of this fact, I would recommend that no changes be made of cooks and food handlers until further notice.
2. Lister bags with suitable coverings only will be used for drinking water; all drinking water will be chlorinated. Soldiers will use individual drinking cups.
3. The handling of cooked food, by kitchen police, will be discontinued.
4. The 8th Company will be quarantined, on account of its being a possible source of infection, until laboratory examinations can be made.
5. Two doors to mess halls will be used (the end door leading into the mess hall, and one leading directly into the kitchen), all other doors to be nailed shut and every available means be used to rid the mess hall of flies. All cooked food will be covered.
6. All kitchen men will thoroughly wash their hands before handling any food.

SEARCH FOR THE SOURCE OF INFECTION

The cases of typhoid fever occurring in Charlotte at this time were thought by the health authorities to be fly borne, owing to the large number of open privies in certain parts of the city.

While the mess hall of the company, in which most of the cases occurred had large numbers of flies when we went to make examination for possible sources of infection, that did not seem likely to be the source, because latrines were at some distance, and were properly cared for and well screened.

What could carry such a massive infection? Was it vegetable, milk, ice or ice cream?

Some of the companies in which the cases occurred placed ice in the drinking water, a large amount of water being prepared either in a galvanized iron can or a barrel. Examinations of water from these barrels and cans showed contamination due to the method of handling the ice, and exposure to dust and flies. These were negative: *B. typhosus* was not isolated. The Public Health Service, having charge of extracantonment work, was examining the milk supply; besides, as will be noted from the histories, milk as a beverage was not used by eleven of these men. A few of the men used the showers and pool at the Charlotte Y. M. C. A. This pool seemed to be very efficiently managed.

Ice supplied to Camp Greene is made from distilled water, and while this ice might become infected in handling, or from dust and dirt getting into the tanks from the shoes of the workmen, this method of distribution was not likely.

It will be noted from the histories that most of the men ate ice cream practically every time they visited Charlotte, and sometimes visited ice cream counters several times during the few hours they were in the city.

Few green vegetables were used in camp; as the histories will show, *most of the men did not have fresh vegetables.*

The camp water supply had been examined at frequent intervals from samples submitted by an officer connected with the office of the camp surgeon, and daily *examination* of water from the laboratory tap was made. As noted above, additional examinations were made of the water supply, and also of the water in the containers used for drinking purposes; *B. typhosus* was not found.

Nine cases occurred in one organization:

One in the medical detachment.

One in the 1st Company (transferred from the 8th Company two weeks before being taken ill).

One in the 3d Company.

One in the 6th Company (transferred from the 8th Company two weeks before being taken ill).

One from the 7th Company (transferred from the 8th Company two weeks before being taken ill).

Two in the 8th Company (transferred from the 8th Company two weeks before being taken ill).

One in the 16th Company (transferred from the 8th Company six weeks before being taken ill).

One in the 18th Company.

The last mentioned patient undoubtedly acquired his infection in Augusta, Ga., and it occurred three months before any other cases; the patient was still in the hospital when the other cases occurred. Repeated cultures made in this case failed, until he was operated on for gallbladder drainage, when a positive culture of *B. typhosus* was obtained.

The patient from the 7th Company (Case 11) was admitted to the hospital, June 17, two weeks before the apparent real outbreak. Tertian malaria was demonstrated two days after admission. Later he was believed also to have typhoid; the fever ran the usual course, but was never proved bacteriologically, although urine and feces were sent to the laboratory at frequent intervals, sometimes every day, but with negative results for *B. typhosus*.

One case occurred in the hospital, this patient having been a bed patient since December, 1917. It was decided to look for a carrier among the nurses and orderlies. Eighty nurses and seventy-two orderlies were examined, all were negative with one exception. A nurse was found to be a carrier, having had typhoid fever seven years before; but this nurse had not been on ward work since April, so that the possibility of her being responsible for this case can be ruled out.

About this time six other cases occurred in recruits, Cases 13 to 18, inclusive. Two had one dose, two had two doses, and two had no inoculations of triple typhoid vaccine.

The question then arose whether there may not have been some defect in the preparation or fault in the administration of the vaccine. In each of our cases this point was therefore investigated. It was found, as shown by the histories, that all had had the regular prophylactic injections within a year at proper intervals, as attested both by the soldiers' statements and by their service records. It was not possible to trace the preparations of vaccines used, but the fact that these soldiers had received their preventive inoculations at different times and at different camps, together with the known care with which the Army vaccine is prepared, renders it unlikely that the failure of immunity was due to failure to receive the standard vaccine in standard doses.

TABLE 1.—CULTURAL EXAMINATIONS

* Month refers to time when inoculations were completed.

† In this table, 0 means negative; the figures in parentheses denote the first examination that gave positive findings. In Case 6 a positive culture was obtained *following operation.*

‡ Examination for cook, May 6, negative. Examination for hookworm, May 15, positive; *negative obtained after treatment.* Diagnosis for typhoid fever, *July 4.*

Much more strongly suggested was the exposure of these patients to massive doses of the infecting agent, against which the immunity produced by the standard process of vaccination was inadequate. Most of the cases occurred in a short period of time, coincident with a mild epidemic in the nearby city of Charlotte; most of them occurred in one organization. While, as will be described later, no conclusive source of infection was proved, the assumption was warranted that some source of marked virulence existed.

In attempting to identify such a source of massive infection, the possible presence of a carrier or carriers was first considered. The records showed that 159 men in the organization in which the cases occurred had the preliminary routine examination made for carriers before being accepted as cooks, but there was some question whether some handlers of food had been included. With the discovery of cases, further examinations of stools was instituted, specimens being obtained from sixty-four cooks and food handlers and other soldiers in the organization most concerned; but this organization was moved from camp before all examinations planned could be carried out. However, no carriers were found during this examination.

Table 1 shows the results of cultural examinations of blood, urine and feces. It is to be noted that positive blood cultures were obtained in thirteen cases, or 72.2 per cent.; urine cultures in thirteen cases, or 72.2 per cent., and feces in only nine cases, or 50 per cent.

BACTERIOLOGIC TECHNIC

Blood Cultures.—Ten c.c. of blood were drawn into a Lüer syringe and then cultivated in a bottle containing 100 c.c. of plain bouillon. After from twenty-four to forty-eight hours a loop was streaked on freshly poured Endo plates and these incubated for twenty-four hours. Suspicious colonies on Endo plates were fished to Russell medium and finally subjected to agglutination tests and carbohydrate reaction, glucose, saccharose, lactose, maltose, mannite, and litmus milk being used. Endo plates more than twenty-four hours old were never used. Frequently two and three Endo plates were made, the same spreader being used without reinoculation so that well isolated colonies could be studied.

Feces.—Bile mediums and also mediums recommended by Teague, 30 per cent. glycerin in physiologic sodium chlorid solution, was used. A small portion of feces about the size of a hickory nut was placed in 20 c.c. of either of the foregoing mediums, the specimen broken up, and incubated over night. Freshly poured Endo plates were then streaked, incubated twenty-four hours, and the same technic followed as noted under blood cultures.

Urine.—The same technic was used as with feces except that specimens were collected directly into bottles containing the culture mediums and incubated from twenty-four to forty-eight hours before plating.

All cultures were sent to the Army Medical School for confirmatory diagnosis.

Cross-agglutination tests were run on two different occasions, patient's serum and cultures being used (Tables 2 and 3). The results would indicate the possibility that a vaccine containing a number of strains might give greater protection.

The variability of agglutinations with freshly isolated cultures of *B. typhosus* was given some attention. Tests were thus made:

1. Agar cultures grown twenty-four hours at 37.5 C.
2. Broth cultures grown twenty-four hours at 37.5 C.
3. Dreyer's[5] agglutinating fluid. Broth cultures were transplanted for two weeks at daily intervals, a few drops of the last transplant were planted into bottles containing 100 c.c. of broth, incubated for twenty-four hours at 37.5 C., and then 0.1 c.c. of liquor formaldehydi was added. The bottles were placed in the ice box, shaken daily for a few minutes, and after a period of five days were used in the agglutination tests.

The few tests made showed a wide variation both as regards individual strains and as regards the preparation of the agglutinating fluid by different methods.

Our work confirms that of others, showing the desirability of using standard agglutinating fluid for Widal tests. The work also strongly suggests that the same method should be used in checking the agglutination of patient's serum with the homologous strain.[6]

COMMENT

It is to be concluded, therefore, that occasional cases occur in which the usual preventive inoculations against typhoid fever fail to protect against the disease, most probably on account of the ingestion of virulent organisms in massive doses. To eliminate such occurrences, sanitary precautions should prevail; but they can succeed only by constant attention to the guarding of food and drink against contamination. Serious contaminations of water supply and of milk on a large scale near the source can ordinarily be prevented by the efforts of sanitary officers, civil and military, working in cooperation. The contamination of water, ice, milk and food on a smaller scale by carriers among food handlers and flies, however, is a matter that demands more laborious and detailed attention. Success in the protection of latrines and in the control of flies is never absolute, but only relative and in proportion to the care devoted to the subject. No false sense of security from typhoid vaccination should be permitted to relax vigilance in this direction. But more important still, in our opinion, is the supervision of food handlers, not only to insure cleanliness, but also by bacteriologic tests of each individual to exclude the admission of a carrier to any position from which he can contaminate the food or drink of his company. It is to be realized, moreover, that a single bacteriologic test, if negative, is not absolute protection, as illustrated by the number of negative feces examinations even in acute cases. Inquiry should therefore be made in all cases as to typhoid fever in the past, and when positive or suggestive history is found, the person should be excluded from handling food until repeated cultures have proved negative. More difficult even than the control of the company mess is the supervision of restaurants and lunch counters outside of the camp. The only way of preventing danger from such sources is to prevent soldiers from taking food or drink outside of their own mess, whenever typhoid fever is known to be occurring in the neighborhood.

CONCLUSIONS

1. Care should be taken that cooks and food handlers are not changed and new ones put in their places without examination for carriers of *B. typhosus*.

2. Special inquiry should be made by the surgeon of all prospective cooks and food handlers with reference to their having had typhoid fever, and

[6] Library facilities have been so meager that we are unable to mention the work of other authors who have published reports of similar work.

note of this made when specimens are submitted for examinations.

3. Repeated examinations should be made of prospective food handlers whose history is suggestive of typhoid fever before the men are accepted for such work.

4. Clinical cases of typhoid fever should have intensive study made of both urine and feces, as is shown in Case 7, in which the patient became a carrier.

THE CLINICAL SIGNIFICANCE OF LYMPHOID HYPERPLASIA OF THE APPENDIX

DOUGLAS SYMMERS, M.D.
Professor of Pathology, University and Bellevue Hospital Medical College; Director of Laboratories, Bellevue and Allied Hospitals

WITH THE COLLABORATION OF

MORRIS GREENBERG, M.D.
Intern, Bellevue Hospital

NEW YORK

In the course of the past fifteen years, one of us, working in the pathologic laboratories at the New York and Bellevue Hospitals, has been almost daily impressed by the fact that, of all appendixes removed at operation, a very considerable number revealed no noteworthy microscopic alterations other than lymphoid hyperplasia, with or without the association of moderate sclerotic changes in the connective tissues. Signs of inflammatory exudation in the appendix were missing, and yet the patients had been subjected to operation because of definite symptoms of appendical disturbances of a subacute or chronic nature. With the exception of a paper by Barss,[1] to whom full credit should be given for first calling attention to the significance of these changes, the literature on the subject appears to be silent. Barss removed seven such appendixes at operation, all of them from children under the age of 14. In our records at Bellevue Hospital, which include the results of the microscopic examination of several thousand appendixes, the occurrence of excessive lymphoid hyperplasia was described as the sole or the predominant change in about 10 per cent. of the total number. We have correlated the clinical and histologic data in a series of twenty cases, no larger number having been investigated for the reason that the historical details were found to be monotonously alike. There seems to be no doubt, however, that the condition constitutes a syndrome of practical importance from the standpoint of its relationship to status lymphaticus and the advisability of operative interference.

FINDINGS IN TWENTY CASES

Of the twenty cases investigated by us, ten occurred in females and ten in males. The ages varied from 2 to 30 years, although additional and exceptional instances have come to our attention in which identical microscopic changes occurred in the appendix as late as the thirty-seventh year. The average age in the series of twenty cases was 17½ years. In all, the history was to the effect that the patients had suffered from two to eight attacks referable to the region of the appendix. In every instance the leukocytes were within normal limits, the differential count disclosing no noteworthy variations in the number of polymorphonuclear cells. The highest count was in a child of 2 years, in whom the leukocytes numbered 14,000, of which 79 per cent. were polymorphonuclear neutrophils. The lowest count was in a boy of 17, the leukocytes numbering 6,000, of which 70 per cent. were neutrophils. In every one of the twenty cases, operation was followed by recovery. From an examination of the clinical histories, it was furthermore developed that the patients had complained of attacks, recurring at intervals of weeks or months, characterized by cramplike pain or by pain and moderate tenderness in the region of McBurney's point, lasting for several hours or days. Muscular rigidity, if present at all, was seldom of marked intensity. Nausea was not uncommon, but vomiting rarely occurred. The temperature was normal in every instance, and the pulse rarely exceeded 80 or 90 beats to the minute. Headache and constipation were fairly common.

Pathologically, the appendixes presented no naked eye or microscopic changes indicative of inflammatory exudate. Some of them were apparently slightly enlarged, others normal in size. The serosa was pale and smooth, a few minute congested vessels appearing at intervals. On section, the lumen was almost immediately found to be diminished in size or even occluded. The mucosa was thickened and swollen, pale or yellowish, and in it pinpoint sized, or slightly larger, rounded, cream-colored bodies were to be detected by the unaided eye. These, on microscopic examination, were found to represent hyperplastic lymphoid follicles, in practically every one of which were large, rounded, circumscribed bodies corresponding to the so-called germinal areas of Fleming. These, in turn, on microscopic investigation, were seen to be made up of innumerable loosely arranged cells, surrounded by a thick mantling of small, densely packed, richly nucleated, and otherwise intact lymphoid cells. The loosely packed cells in the center of the lymphoid nodules varied greatly in size and shape and in the chromatic richness of their nuclei, some of which were pyknotic, while others showed the effects of chromatolysis. Many of the cell forms as well as their nuclei were distorted in outline, and all of them were obviously in the process of disintegration.

In a second variety of appendix removed from individuals who had suffered several attacks of colic in the region of McBurney's point, the hyperplastic and centrally disintegrating lymphoid follicles were supported by a sclerotic or even a hyaline connective tissue framework in which large fat vacuoles sometimes occurred.

In a third variety, occurring oftenest in older patients, the appendix was found to be diminished in size, sometimes reduced to a smooth, pale, cordlike structure which, on microscopic examination, presented only a few atrophic lymphoid follicles and almost complete connective tissue replacement of the mucosa and obliteration of the lumen.

CLINICAL RECOGNITION

Bearing on the clinical recognition of this variety of appendical lesion are several facts of practical significance. In the first place, the occurrence in the germinal follicles of degenerative lesions of the sort described is apparently best explained as a histologic indication of status lymphaticus. These degenerative foci were first described in status lymphaticus by

---

[1] Barss, Harold de B.: Lymphatic Disease in Children Simulating Appendicitis, Am. J. Dis. Child. 15: 421 (June) 1918.

Lartigau,[2] then by Blumer,[3] and by Norris[4] and his associates[5] in this laboratory, where, in an experience covering a period of more than twelve years, including the systematic microscopic examination of tissues from more than 5,000 necropsies, among them nearly 300 cases of status lymphaticus, we have yet to find the same changes in the lymph nodes in any other condition. These foci may be demonstrated in status lymphaticus wherever lymphoid tissues occur. They are encountered with noticeable frequency in the ileum, the solitary and agminated follicles of which are, of course, in intimate geographic relationship with the lymphoid structures of the appendix. Wherever encountered, these degenerative foci appear to provide visual evidence of that instability of the lymphoid tissues by which status lymphaticus is attended. In the appendix of subjects of status lymphaticus, sudden increase in the cellular content of the lymphoid follicles, occurring at irregular intervals and at an age when the lymphoid tissues as a whole are subject to elastic structural variations, even in physiologic conditions, coupled with the simultaneous eruption of dozens of circumscribed necroses, suffices to explain the symptoms with which this variety of appendical lesion is associated, the absence of changes in the pulse, temperature and blood count, the mildness of the clinical phenomena and the lack of exudate into the tissues of the appendix serving effectually to exclude any suggestion of inflammatory reaction as a possible factor in the process. In the sclerotic appendixes, the overgrowth of connective tissue is to be interpreted as a change secondary to the mechanical effects of frequently recurring enlargement of the lymphoid follicles, the intermittent disturbances thus produced so reacting on the interstitial framework of the appendix as mechanically to effect a simple fibrosis, the ultimate result of which is to bring about more or less complete replacement of the mucosa and submucosa.

Every properly trained medical student recognizes at a glance the so-called phthisical chest, the physical conformation of which has been known for generations, and no one denies its existence or disputes its significance. Not every individual with such a chest develops tuberculosis, however, and not every individual stricken with tuberculosis is provided with a thorax thus architecturally defective. Much the same criticism is applicable to the living subject of status lymphaticus, whose bodily configuration presents deviations from the normal that are constant and recognizable at a glance. This fact, pointed out not long ago by Norris, has been largely ignored, partly, I take it, because it is of recent birth and because this is the day in which the art of inspection no longer occupies the same dignified position among diagnostic methods as it did when physicians depended more on the acuteness of their special senses and less on technical devices.

Thirty years ago, Langerhans' child died suddenly after the administration of antitoxin, a victim of status lymphaticus, and since that time textbook makers have so persistently emphasized the association of sudden death with status lymphaticus that its broader significance has been lost. As a matter of fact, sudden death in status lymphaticus is a comparatively uncommon event; but, when it does occur, the astonishing rapidity of the blow and the unexpected circumstances in which it is delivered are spectacular and exceedingly impressive. Not every individual with the stigmata of status lymphaticus drops dead if pricked with a needle—some, unfortunately, do succumb to this or equally trivial injuries. Moreover, certain subjects of status lymphaticus are not only highly susceptible to infections, notably cerebrospinal meningitis and diphtheria, but in them such infections are apt to pursue a rapidly fatal course. On the other hand, it is, I believe, safe to say that many subjects of status lymphaticus are not only capable of withstanding injuries, both slight and severe, but infections as well.

In the pathologic laboratories at Bellevue Hospital, those visiting physicians and interns who make it a practice to be present at necropsies, are so well acquainted with the changes in bodily configuration of status lymphaticus and have so often seen these structural peculiarities brought into definite postmortem correlation with persistence or enlargement of the thymus gland, hyperplasia of the lymphoid follicles in the spleen, intestine and elsewhere, and hypoplasia of the aorta and of the vessels of the brain that, to them, status lymphaticus is a demonstrated reality, and their knowledge of its existence frequently is applied to problems presented by the patients in the ward. Its surgical importance, however, has received scant attention, either at Bellevue Hospital or elsewhere, so that we are unable to offer any evidence from the available records of the hospital as to the configuration of those patients from whom were removed the appendixes now under consideration.

In the clinical conglomerate of scrofula the elder Gross long ago recognized the angelic child, in whom he pointed out the existence of a so-called lymphatic constitution. It is now known that children of this type are of the category of status lymphaticus. The angelic child may be described as delicately molded but beautifully proportioned, often excellently well nourished, blue eyed or brown, with long lashes, finely chiseled features, transparent cheeks and rapid mutations in coloring, thin lips, smooth skin and silklike hair, shapely limbs and quick, graceful movements, narrow waisted, mentally alert, often precocious. Still other children, with the stigmata of status lymphaticus, are physically and mentally sluggish, coarse featured and sometimes rachitic, but even in these the skin may be fine and the limbs shapely.

After puberty, the clinical recognition of status lymphaticus is even more easily accomplished. In the male the general conformation of the body is of two types: In one—and more particularly is this true of negroes, although by no means confined to them—a magnificent array of muscles is molded over a body of fine proportions and easy, streaming outlines. Some of the most striking examples of physical beauty are to be sought in subjects of status lymphaticus. In the second type, however, one is apt to receive the impression of a form more nearly approaching a rectangle, the squared shoulders, rather flat chest, and indifferent muscular development lending somewhat ungainly proportions to a body no less confidently to be identified, however, as of the status lymphaticus type; for in both the skin is of almost matchless delicacy; the facial and axillary hairs are scantily developed; the thoracic hairs are few or absent, and those of the pubes assume the distribution of the female, that is to say, they are sharply defined in a transverse direction and do not tend to grow toward the umbilicus; the penis is often small and the glans acorn shaped, while the waist line is slender and the thighs arching. In a word, the general appearance of the male body approaches that of the female.

[4] Norris, in Johnson's Surgical Diagnosis 3: 704, 1910.

[5] Symmers, Douglas: Status Lymphaticus, Am. J. M. Sc. 156: 40, 1918; The Cause of Sudden Death in Status Lymphaticus, Am. J. Dis. Child. 14: 463 (December) 1917.

In the female, the recognition of status lymphaticus by inspection is rather more difficult; but the diagnosis may be made with relative assurance by the unusually delicate texture of the skin, by accentuation of the normally graceful outlines of the body, and by the presence of small axillary pads with the scanty growth of hair on them.

FREQUENCY OF STATUS LYMPHATICUS

In the first 4,000 necropsies performed at Bellevue Hospital, status lymphaticus was encountered 249 times (6.2 per cent.).[5] Of this number, thirty-two were under the age of 10, eighty-two were between 11 and 30, ninety-eight between 31 and 50, and thirty-seven over 50. In addition to the occurrence of sudden death in subjects in whom, at necropsy, there is no assignable anatomic cause, status lymphaticus is not uncommonly associated with sudden death in young adults, owing to rupture of congenitally hypoplastic cerebral vessels, occurring spontaneously or as a result of heavy lifting, straining at stool, the tension of argument, fighting, and the like, and there is little doubt that certain of the otherwise unexplained aerial accidents that occurred in the course of the war were due to the same cause. Moreover, hypoplasia of the smaller blood vessels is apparently an element of danger in workers in compressed air, five cases of caisson disease having been examined postmortem at Bellevue Hospital in individuals showing the characteristic stigmata of status lymphaticus.

Emerson,[6] working in the alcoholic wards at Bellevue Hospital, examined 1,000 patients suffering from the effects of attempted suicide and from cocain, morphin, heroin, alcohol and similar habituating drugs. Of this number, 220 (22 per cent.) showed most or all of the physical stigmata of status lymphaticus. I have had occasion to note the characteristic configuration of status lymphaticus in sufferers from neurasthenia and in certain primitive races. In the necropsy rooms at Bellevue Hospital, which are utilized by the several medical examiners and by Dr. Schultze, of the district attorney's office, for the performance of necropsies in medicolegal cases, it is a matter of almost daily observation that suicides and degenerates, and gunmen and other criminals who have met death by violence, present the characteristic conformation and anatomic changes of status lymphaticus. According to the combined statistics of Bartels[7] and Miloslavich,[8] amounting to 232 cases of suicide, 80.5 per cent. showed the signs of status lymphaticus at necropsy. Among epileptics and the insane the condition is common (Karpas).

The association of status lymphaticus and exophthalmic goiter, while not constant, is common, and is particularly noteworthy in connection with the incidence of status lymphaticus among the emotionally unstable. In six cases of exophthalmic goiter investigated postmortem at Bellevue Hospital, signs of status lymphaticus were present in five, in some better developed than in others. Capelle[9] collected sixty instances of exophthalmic goiter from the literature. In 44 per cent. the patients died from intercurrent affections, and in all of them the thymus was persistent and hyperplastic. Of those dying of exophthalmic goiter without associated lesions, 82 per cent. presented enlargement of the thymus, while in cases of sudden death following operation for removal of the thyroid, the thymus was hyperplastic in all.

It has been shown by Daut,[10] Elser[11] and Symmers[5] that a large percentage of all cases of diphtheria and cerebrospinal meningitis occur in subjects of status lymphaticus, and that in them death is apt to follow a noticeably brief illness. Our records at Bellevue Hospital also show that typhoid fever in subjects of status lymphaticus is apt to pursue a rapidly fatal course, although this is by no means constant, for Dr. Van Horne Norrie tells me that he has not infrequently observed such individuals safely through. It is also our experience that about 10 per cent. of all cases of acute infective endocarditis occur in subjects of status lymphaticus—a point worthy of remembrance in dealing with otherwise obscure symptoms of infection in such individuals.

Finally, the clinical significance of status lymphaticus is enforced by the observation that excessive lymphoid hyperplasia of the appendix, associated with the presence of degenerative or necrotic lesions in the germinal areas, occurs so often in children or young adults giving a history of repeated and relatively mild attacks referable to the region of the appendix as to indicate the desirability of routine inspection of all such individuals for the physical attributes of status lymphaticus. This is important in view of the possibility of sudden death under anesthesia or operation and of infection. In such cases the clinical indications for operation are not imperative, and the histology of the appendix shows that the changes do not tend in the direction of perforation, but toward fibrosis. Whether it is best to allow such patients to pass through the annoyance of successive attacks, rather than to accept the not altogether remote risk of sudden death or of infection, is a question which, of course, is to be determined in each case as it arises.

CONCLUSION

There is a clinically recognizable syndrome referable to lymphoid hyperplasia of the appendix, attended by degenerative or necrotic lesions in the germinal areas, with or without sclerosis of the interstitial tissues of the submucosa. The syndrome is marked by repeated attacks of appendical colic, occurring at intervals of days, weeks or months, but is not accompanied by noteworthy changes in pulse, temperature or blood count, and is encountered most frequently in children or young adults. It is probably peculiar to subjects of status lymphaticus.

The Problem of the Mental Defective.—Mental defectiveness is hereditary and constitutional, and consequently not amenable to our preachings, asylums, reformatories, penitentiaries, etc. We must ever bear in mind that each year a new quota of defectives is born with statistical regularity. They pass through the hands of parents, then the pedagogues, the theologians, the physicians, the social workers, the employers, the courts, the prisons, and back on society, each one in turn passing them up to the next, and no one willing to acknowledge their impotency in the face of mental defectiveness.—Hickson.

STATISTICAL STUDY OF SIMPLE AND TOXIC GOITER AT JEFFERSON BARRACKS, MO.

FRED M. SMITH, M.D. (Chicago)
Lieutenant, M. C., U. S. Army
JEFFERSON BARRACKS, MO.

Between April 1 and Sept. 1, 1918, 65,507 men passed through the examining barracks at Jefferson Barracks. An enlargement of the thyroid gland was noted in 1,074 instances (1.63 per cent.). In 116 cases (10.7 per cent.) there were toxic symptoms. These men were rejected with a diagnosis of hyperthyroidism or exophthalmic goiter, depending on whether or not exophthalmos was present.

GEOGRAPHIC DISTRIBUTION

Men from fifteen different states—Arkansas, Illinois, Iowa, Indiana, Kansas, Michigan, Minnesota, Missouri, Nebraska, North Dakota, Oklahoma, South Dakota, Tennessee, Texas and Wisconsin—are included in these figures. The accompanying table shows a number in which there were thyroid enlargements, the percentage of thyroid enlargement in the number examined, the number of toxic goiters, and the percentage of goiter cases in which there were toxic symptoms. It is noted that Oklahoma has the highest percentage (38 per cent.) of goiters, followed in order by Texas, 20 per cent; Tennessee, 11; North Dakota, 8.7; Nebraska, 8; Indiana, 6.6; Iowa, 6.2; South Dakota, 6.2; Michigan, 3.3; Wisconsin, 2.7; Arkansas, 2.3; Minnesota, 1.3; Missouri, 1.1; Kansas, 1.1, and Illinois 0.6 per cent. Texas ranks highest in percentage (20 per cent.) of goiters in which there were toxic symptoms, followed in order by North Dakota, 19 per cent.; Kansas, 14.2; Wisconsin, 13; Missouri, 12.6; Tennessee, 12.5; Iowa, 11.2; Arkansas, 10.5; Illinois, 10.1; Nebraska, 10; Oklahoma, 8.3; Indiana, 7.2; South Dakota, 4.1; Minnesota, 3.8, and Michigan, 0 per cent.

INCIDENCE OF GOITER

States	Number of Men Examined	Number of Goiters	Per Cent. of the Number Examined	Number of Toxic Goiters	Percentage of Goiters with Toxic Symptoms
Arkansas	4,375	104	2.3	11	10.5
Illinois	24,836	158	0.63	16	10.1
Iowa	998	62	6.2	7	11.2
Indiana	1,465	97	6.6	7	7.2
Kansas	1,792	21	1.1	3	14.2
Michigan	211	7	3.3	0	0
Minnesota	7,551	78	1.3	3	3.8
Missouri	19,577	221	1.1	28	12.6
Nebraska	124	10	8.0	1	10.0
North Dakota	523	46	8.7	9	19.0
Oklahoma	221	84	38.0	7	8.3
South Dakota	387	24	6.2	1	4.1
Tennessee	485	56	11.0	7	12.5
Texas	141	29	20.0	6	20.0
Wisconsin	2,821	77	2.7	10	13.0
Grand total	65,507	1,074	1.63	116	10.8

The men from whom these figures are compiled are between the ages of 18 and 31 years and, as the table indicates, represent widely scattered areas of a wide section of the country, none of which are free from goiter. Contrary to the prevailing conception, the states in the Great Lakes region stand rather low in the list with regard to the percentage both of simple and of toxic goiter.

TOXIC GOITER

In 100 cases of toxic goiter (hyperthyroidism or exophthalmic goiter) a careful study was made of subjective symptoms and physical findings.

Fifteen (15 per cent.) of these men apparently felt as well as ever, except that they had noticed they were more irritable than usual and had been wakeful at nights during the past few months. Sixty-six complained of palpitation of the heart. This and nervousness were the most common subjective symptoms. Fifty-eight had attacks of dizziness. Fifty-four became short of breath easily and had a feeling of exhaustion on exercise. Thirty-nine complained of precordial pain. Twenty-nine perspired very freely and had hot flushes of the face and hands. These symptoms were all aggravated by physical strain and excitement. The nervous strain of the examination and the new environment was especially noticeable.

DURATION OF THE SYMPTOMS

In twenty-five men (25 per cent.) the symptoms had been noticed for two years or more; sixty-four, one year or more, and ten, less than one year. The remaining fifteen were unable to state the time of the onset of their trouble.

OCCUPATION AND ITS EFFECT

Forty-six men (46 per cent.) stated that they did hard physical labor. Many of these men added, however, that it was becoming very difficult for them to do their work. Fifteen had recently had to change to light work. Thirty-six did light work, and nineteen sedentary work. The men in a light and sedentary occupation were, in most instances, having no difficulty.

PHYSICAL FINDINGS

The tachycardia attracted the attention of the examiner and was invariably the reason given for referring the subject to the cardiovascular board. The pulse rate in a recumbent position before exercise ranged from 90 to 160 per minute. In only six instances (6 per cent.) was the rate below 100. In fifteen, it was from 100 to 110; sixteen, from 110 to 120; twenty-two, from 120 to 130; twenty, from 130 to 140; sixteen, from 140 to 150, and two, from 150 to 160 a minute. The pulse rate as a rule was very unstable, increasing rapidly with exercise or excitement. The latter was often noticed when the stethoscope was placed to the precordium.

ENLARGEMENT OF THE THYROID GLAND

The thyroid gland was enlarged in every instance. In many the enlargement was slight, and in few cases well down under the sternum. Usually the subject was not aware of any increase in the size of the neck.

EYE SYMPTOMS

In fifty-three cases (53 per cent.) there was an exophthalmos; these men were discharged with a diagnosis of exophthalmic goiter. In these the subjective symptoms were more marked. The remaining forty-seven had either staring expression (Stellwag), lagging of the lids (von Graefe) or poor convergence (Moebius), or all three signs.

A fine tremor of the hands was a constant finding in all cases.

The apex impulse was in the fifth interspace in every instance, varying from 6.5 to 8.5 cm. from the midsternal line. In forty-nine cases there was a soft systolic murmur at the apex which was often heard at the base on the left side. In every instance this was cardiorespiratory in type.

The systolic blood pressure was usually increased. In fifty-one cases the systolic pressure was above 140 mm. of mercury. Of these, twenty-nine were between 140 and 150; eleven, 150 and 160; eight, 160 and 170, and three, 170 and 180. In forty-nine cases the systolic pressure was between 110 and 140. Of these there were two between 110 and 120; twenty-five, 120 and 130, and twenty-two, 130 and 140 mm. of mercury.

COMMENT

According to these statistics, goiter is fairly prevalent in the young male population throughout a large section of the central and western portion of the United States. The percentage is even higher in Texas and Oklahoma than in the Great Lakes region, which is contrary to the prevailing conception. Since these statistics were compiled, men have passed through the examining barracks from Idaho and Montana. A high percentage of them had goiter. We have been told that goiter is very common in the soldiers of Camp Lewis. In the examination of the Thirty-Eighth Division at Camp Shelby, composed of 22,622 men from Indiana, Kentucky and West Virginia, Musser[1] made a diagnosis of hyperthyroidism in ninety-seven cases (0.4 per cent.). Jones,[2] in an article based on the study of 407 cases in the Southeast, states that while goiter is present throughout that section, it is not so common as in the region of the Great Lakes. From this study we conclude that goiter is, no doubt, more common outside of the Great Lakes region than usually considered, and that men are more frequently affected than reports indicate.

DIAGNOSIS

The presence of tachycardia, thyroid enlargement, fine tremor of the hands, eye signs, as lagging lids, staring gaze and poor convergence with increase in systolic blood pressure, in our mind justified a diagnosis of hyperthyroidism. When in addition there is an exophthalmos, as in 57 per cent. of our cases, there is no doubt.

It is often very difficult to differentiate these beginning toxic goiters from irritable heart. This is especially true when the thyroid enlargement is very slight and eye signs are indefinite. The history is important. The men with toxic goiter have some, and perhaps all, of the symptoms of irritable heart. They usually complain much less in the former and, as in 15 per cent. of our cases, had practically no subjective symptoms. The blood pressure affords some assistance. The systolic pressure, in our experience, has not usually been increased in irritable heart, in which no organic basis could be found. On the other hand, 73 per cent. of the men with hyperthyroidism had systolic pressure of over 130 mm. of mercury, and 51 per cent. over 140 mm. In doubtful cases the history and eye signs have been the determining factor, and an increased systolic pressure was used as supporting evidence in favor of hyperthyroidism.

HYPERTHYROIDISM AND MILITARY SERVICE

These men with toxic symptoms are in the early stage of exophthalmic goiter. They rarely ever consult a physician in civil life with the symptoms these men present. Many of them, no doubt, would so adjust themselves to their environment in civil life that they would suffer no inconvenience. In this series 15 per cent. had recently changed to light work.

Physical and mental strain have long been known to be important factors in precipitating or aggravating the symptoms of toxic goiter. These factors in military training would most probably break down many of these men. Major L. M. Warfield and I have observed twenty cases in the hospital, where they were given graded exercises. Nine of these men were sent to the hospital from the examining barracks suspected of having hyperthyroidism. In every instance the subjective symptoms grew progressively worse. No doubt the first few days in an army post aggravated the already incipient symptoms. Eleven men were sent to the hospital because they were no longer able to do their work satisfactorily. All had marked symptoms of hyperthyroidism. Seven had definite exophthalmos. Four stated that they had no symptoms prior to entrance in the Army. The remaining seven date their trouble back to civil life, but contend that they had become markedly worse since they began their military training. The average service given by these men was one and a half months. These observations are too few to justify definite conclusions. They are, however, confirmatory evidence in favor of the prevailing conception that the toxic goiter is a poor military risk.

ACUTE LYMPHATIC LEUKEMIA COMPLICATING PULMONARY TUBERCULOSIS *

MICHAEL L. RYAN, M.D.

SYRACUSE, N. Y.

The etiology of leukemia, although studied in detail by numerous investigators, still remains obscure.

Malaria, pregnancy, syphilis, splenic trauma and tuberculosis are regarded by many as the exciting agent. Whether these conditions are causative or merely coincident cannot be definitely ascertained at present, owing to the comparatively rare incidence of the disease, and the relatively small number of cases thus far reported.

Still others believe that the condition is due to a specific micro-organism. Ward,[1] who has made an intensive study to determine whether or not infection is the cause, came to a negative conclusion, basing his opinion on these observations:

1. There is a congenital form of leukemia found in children of normal parents.
2. Leukemic parents have never been known to transmit the disease to their offspring.
3. Very few instances of supposed transmission of the disease have occurred.
4. Leukemia has a marked preference for a particular age and sex, and in this differs from infectious diseases.

Cameron recites a case that tends to show that leukemia is due to infection or to the existence of a strong hereditary tendency. The grandmother and mother of the patient, as well as a brother, suffered from symptoms strongly suggestive of leukemia. One of the patient's children died of the disease previous to its development in the mother, and the death of a second child occurred later from the same cause.

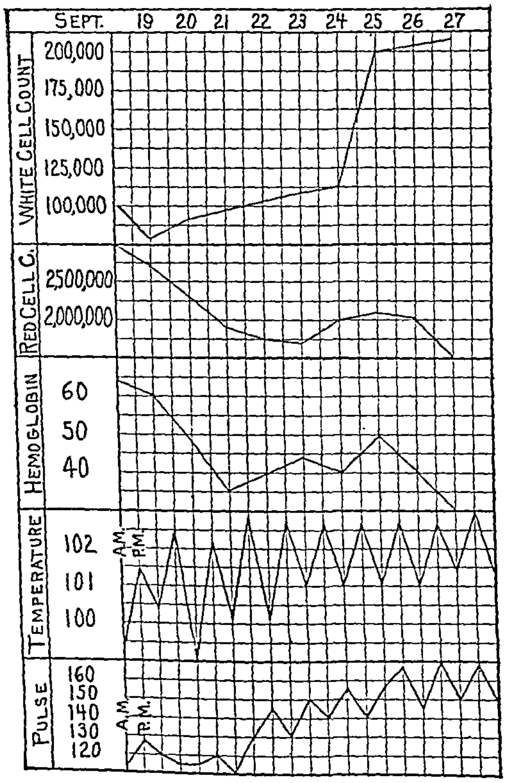
---

* From the New York State Hospital for Incipient Pulmonary Tuberculosis, *Ray Brook, N. Y.*

[1] Ward, G.: Brit. J. Child. Dis. **14**: 10 (Jan.-March) 1917.

The case in question would suggest more than mere coincidence. Other writers have likewise cited two or more cases of the disease in one household.

Some observers believe that leukemia, as is assumed by some clinicians for carcinoma, is a disease of metabolism. It is pointed out that the onset and termination in certain cases exhibit a marked similarity. The belief that tuberculosis may be an etiologic factor also has its adherents. Dieterle[2] examined a case of primary tuberculosis of the cervical lymph nodes with a wide dissemination of miliary tuberculosis. The case was one of chronic lymphatic myelogenous leukemia with secondary tuberculosis. Tubercle bacilli were found in the venous blood of the right heart on slides stained with carbolfuchsin.



Blood counts, temperature and pulse.

Frankel and Much[3] studied in detail several cases of Hodgkin's disease and lymphatic leukemia. They examined the lymphatic glands in seven cases of lymphatic leukemia by the antiformin method and in each case isolated a thick granular rod, gram-positive but Ziehl negative, morphologically similar to the tubercle bacillus. This bacillus they were unable to cultivate. The results in the cases of Hodgkin's disease were precisely parallel, the bacillus being similar in appearance and staining properties to the one found in the cases of leukemia.

The question naturally arises, after one has noted the results of their investigation as well as that of Dieterle, regarding the possibility of some direct relationship between lymphatic leukemia and tuberculosis. Many students believe that there is some indefinable connection between the two conditions, and for this reason the report of a case of acute lymphatic leukemia complicating chronic tuberculosis may be of interest.

REPORT OF CASE

History.—A woman, aged 30, of Irish-English descent, single, telephone operator, who had had pertussis and measles in early childhood, and pneumonia at 9 years of age with uneventful recovery, complained, in 1914, of feeling weak and tired. Cough and expectoration developed. She did not regain strength. Early in 1916 the condition was recognized as pulmonary tuberculosis, and in May, 1916, the patient was admitted to the New York State Hospital at Ray Brook.

Physical Examination.—The patient was suffering from moderately advanced tuberculosis, and her physical condition was decidedly below par. The left side of the chest from apex to fourth rib, both anteriorly and posteriorly, was very dull to percussion, and fine, dry râles were audible on auscultation. The right apex was slightly involved. Physical examination otherwise was negative. The roentgenogram presented a dense triangular shadow in the left upper three interspaces. The right lung field was clear throughout. The mediastinal contents were displaced slightly to the left. The right leaf of the diaphragm was uniform in outline; the left showed a distinct peak.

Tubercle bacilli were demonstrated in the sputum on several occasions. The blood count was 8,900; hemoglobin, 85 per cent. The white and red cells showed nothing abnormal. Urine examination was negative. The temperature was from 99 to 99.3; the pulse, from 100 to 110; the bowels were constipated; the appetite was fair. The patient seemed quite listless and was of an apprehensive disposition.

Clinical Course.—The pulmonary condition became somewhat better, and in twelve months it was fairly well arrested, the râles in the chest disappearing. The dulness, however, remained, and the general condition of the patient exhibited no marked improvement. There was no appreciable gain in weight. The temperature ranged around 99, and the sputum became negative. Generally she felt fairly well, except for occasional intestinal distress and constipation. No marked change was discernible until early in September, 1918, when the patient began to complain of weakness, and had a temperature of from 99.4 to 99.8 in the evening. September 17, the patient became definitely ill. The temperature rose to 101.2, and was accompanied by nausea and a burning sensation in the stomach. The exacerbation of symptoms was at first attributed to renewed activity of the pulmonary process, although the physical examination did not so indicate. At this time a slight enlargement of the cervical glands was noted. The patient looked anemic, and the conjunctivae were pale. The liver was slightly enlarged; the spleen was not palpable. A blood count was taken September 18, and the result was the discovery of a lymphatic leukemia. The blood count revealed: leukocytes, 103,200; hemoglobin, 65 per cent.; small lymphocytes, 65.5 per cent.; large lymphocytes, 18.5 per cent.; polymorphonuclear neutrophils, 5.5 per cent.; eosinophils, 1.5 per cent.; transition cells, 7.5 per cent.; basophils, 1; normablasts, 0.

From day to day the blood picture changed considerably, as is indicated on the accompanying chart. Some days an improvement was noted only to be followed by a fall in hemoglobin and increase in leukocytes. The lymphatic count varied between 90 and 98 per cent. on the various examinations.

On the night of September 20 the patient had a temperature of 102.2 and vomited a great deal. The following day the axillary, inguinal and cervical glands were much enlarged, and the tonsils became swollen and inflamed, making deglutition difficult.

On the 22d, the patient felt very badly. She had hemoptysis of a few cubic centimeters, and purpuric spots appeared on the abdomen and back. The urine contained a few granular casts and 2 per cent albumin. From this time the clinical manifestations grew progressively worse. Each day she had slight hemorrhages from the mouth; the gums were very tender and bled easily. Herpes appeared on the lips, and the breath became very foul. The urine was thick, and contained large amounts of albumin, and red and white blood cells. The pulse was very fast and bounding, and auscultation elicited a systolic murmur over the mitral area. Headache was almost constantly present, and the tongue was foully coated. During this entire period the spleen palpable, and the liver was enlarged only 1 inch below the costal margin. No ascites was evident. The lymphatic glands, however, became progressively larger from day to day.

---

[2] Dieterle, R. R.: J. Infect. Dis. 19: 263 (August) 1916; abstr. J. A. M. A. 67: 638 (Aug. 19) 1916.

[3] Frankel and Much: München. med. Wchnschr. 57: 685, 1910.

September 28, the family of the patient insisted on removing her to her home in a distant city, and further progress of the case was not under my supervision. However, the patient survived only fifteen days after the diagnosis was established.

COMMENT

Although no postmortem was held, the clinical picture and repeated examination of the blood are sufficient to establish a diagnosis of acute lymphatic leukemia, malignant in type. One may assume from the clinical notes submitted that in this case pulmonary tuberculosis was the initial disease, and that after an illness of two years, the patient developed acute lymphatic leukemia, of which she died. Possibly histologic examination of the affected glands might have shown some association between the leukemia and the coexistent tuberculosis.

PURGING BEFORE AND AFTER ABDOMINAL SECTION

HENRY T. BYFORD, M.D., F.R.C.S.
CHICAGO

A few years ago the drift of surgery, as a result of the introduction of anesthesia and the adoption of antisepsis, was toward the development of technic and the perfection of methods. Coincidentally much attention was given to the elaboration of the preparatory and after-treatment. Many things were recommended and more or less extensively employed for the purpose of fortifying the patient for the operative ordeal, and of neutralizing the untoward effects. As surgical technic improved and methods were perfected, one after another, these measures were found to be no longer necessary and were eliminated, and the preparatory and after-treatment assumed a simplified, more or less routine character.

One of the routine measures that has survived is the preoperative and postoperative purgation. Yet there are those who are now seeking to give this attempted imitation of a simple process of nature its *coup de grâce*. They not only declare it unnecessary, but also attempt to prove by arguments and experimentation that it is harmful in its effects. I will restrict my remarks to purgation in cases of intra-abdominal surgery in which the opening of the peritoneal cavity makes the condition of the intestinal canal a matter of considerable importance.

PREPARATORY PURGING

Before we can discuss preparatory purging intelligently, we must define what we wish to do by it, and how we do it. I suppose that the main purpose is to cleanse the bowels of any gas or feces that might interfere with the attainment of the best results from our operative work. Another is to have a comparatively empty colon in those cases in which it may be desirable to keep our patient constipated for two or three days after the operation.

The main argument against such purgation is that it seldom cleanses the bowels and more often increases than diminishes the abdominal distention; and this really seems to be the case in many instances. An examination of the way in which it is ordinarily carried out in practice will show why: When a plumber cleans out a sewer, he does not put dirt into it at the same time because he knows better; but when the average surgeon prescribes a laxative to clear out the bowels, he allows food to be taken a short time before the laxative is given and permits or orders more to be taken before the laxative has quit working. The result is that instead of cleansing the bowels, the laxative merely moves everything onward. It expels old fecal matter and gas together with the digestive secretions and ferments while the stomach is delivering food into the duodenum. This food not only does not find the normal secretions for its digestion, but it is rushed onward too fast for digestion and arrives in the colon as food for bacteria rather than for the patient. Not only is this true, but more food is usually given before the intestine has recovered from its fatigue sufficiently to take care of it. As a consequence it becomes distended, whether it has been so previously or not. If such is the ordinary preparatory purging—and I think it is—then much argument and experimentation is not required to condemn it.

This may be said to conclude the argument from the objector's standpoint, but it does not touch on the merits of the question. The question is whether a laxative can be given to accomplish what we give it for, and if so how. I think it can, if what I shall call the four R's are observed, namely, the right laxative, in the right dose, at the right time, and under the right conditions.

The Right Conditions.—To begin with the last R mentioned, the surgeon or some one else should prescribe the conditions under which the desired results of the laxative can be secured. The material for the renewed formation of gas should be kept out of the alimentary canal; the last food that the patient takes before taking the laxative should have time to leave the duodenum and to be absorbed before the rapid peristalsis connected with purgation begins. After the purgation has ceased, none but easily digested food in properly regulated quantities should be given, such, for instance, as the quickly absorbable forms of sugar, meat extracts or nutritive wines or, if the patient is very weak, predigested food, until the upper intestine has sufficiently recovered from its fatigue to assume normal function, which may be before or not until after the operation, according to the requirements of the patient. The fact that such severe restriction of the diet is required, however, constitutes an indication for limiting our attempt at securing a collapsed or partially collapsed intestine to those cases in which the intestine is not already sufficiently collapsed and in which the conditions of the operation require it.

The Right Time.—The timing of the laxative must be such that any residual gas that may be left will have a chance to be absorbed. Thus, for a forenoon operation, the laxative will have to be given early on the day before or in some cases the night before that. For an afternoon operation, it will ordinarily be required the night before the operation, and sometimes earlier. If the object in view is to get the patient in a good condition for the operation, it may have to be given three or four days before; and the alimentary canal, for two or three days may have to be allowed to functionate normally and under low pressure, if I may be allowed to use the term.

The Right Laxative and the Right Dose.—On account of the variations in the character of the different operations and the differences in the condition of patients, the kind and amount of purgation should be adapted to the requirements of the concrete case. One abdominal section may require a low incision, another a high one; one a large incision, another a short one; one patient may require work at the bottom of the pelvis, another at the surface; one intestinal work, another none; one operation may be a long one, another a short one; one may require general anesthesia, another local only; that is, in one patient no attention to the bowels may be required even though they are somewhat distended, while in another a carefully conducted preliminary purgation may be essential to reduce the distention and enable the operator to do good work.

Again, a patient may come to us half starved and with collapsed intestine, and may not even need an enema, or perhaps only a mild stimulating one to relieve the sigmoid flexure, or an oxgall enema to soften and remove a few hard fecal masses from a dry and sluggish rectum. In such a case only harm could come from ordinary routine purgation and dieting. On the other hand, a patient may be a strong, hearty eater, with a full abdomen and powerful abdominal muscles who requires active purgation to remove foul gases and diminish intra-abdominal pressure, and who can stand any amount of dieting. One patient may be constipated habitually and on that account require a powerful laxative, another may always have daily movements and require only an enema; one may have accumulations of fat both inside and outside of the abdominal cavity, while another may be emaciated; one may have idiosyncrasies with regard to laxatives, enemas or anesthetics, another may feel as well after purgation or anesthesia as if he had not taken them, while another may have an organic disease that diminishes his resistance or otherwise makes him a bad risk.

Now, who would advocate sending patients for such a variety of abdominal operations and exhibiting such dissimilar conditions to a hospital, to be prepared in a routine way with routine purgation, perhaps without seeing them again until he finds them on the operating table? And yet such is the case in some of our clinics in large, crowded hospitals, where routine is essential to keep things going, and where individualization may be possible only in private cases.

The laxative should be selected, the dose regulated, the time for its administration chosen, and the conditions under which it acts carefully adjusted to suit the requirements of the concrete case instead of being used in a routine way. Then there will be no occasion for the rejection of purgation in the preparation of patients for abdominal sections.

It should be remembered also that the colon bacillus is not very virulent, that it kills people only under exceptionally favorable circumstances, and that patients in normal condition and without abdominal distention do not require a stirring up with laxatives before an abdominal operation. A restriction of the diet will sometimes promote abdominal flaccidity better without a laxative than with it.

POSTOPERATIVE PURGING

With regard to the question of purgation after abdominal section, the cases may be divided into four classes: (1) those in which the character of the operation requires early purgation; (2) those in which it requires delay in the administration of purgatives; (3) those in which the indications are relative, and (4) those in which the question of purgation is not dependent on the fact that the abdominal cavity has been opened.

1. Those cases require early purgation in which a large incision in the middle or lower zone of the abdomen is made in connection with considerable displacement of intestinal coils, and sufficient intraperitoneal traumatism to give rise to subsequent adhesions. Under such conditions, adhesions of displaced or kinked intestinal loops are liable to form and interfere with through and through peristaltic action and result in obstruction and death. Early purgation helps to maintain a permeable canal until the adhesions have formed and the danger of obstruction has passed.

2. Cases in which there has been resection or extensive repair of the intestine usually require dieting and delay in purgation until a certain amount of protective exudate has had time to seal up the intestinal suture lines.

3. Cases in which sutured or denuded areas have been left are not so liable to the formation of extensive or permanent adhesions if peristaltic action is kept fairly active from the time of the operation. Early purgation may not be necessary, yet it may be desirable. An accumulation of gas may require it in one case, while in another dieting or washing out of the stomach or a postural treatment may suffice.

4. Cases in which the incision has been small, with but little exposure or manipulation of the intestine and in which all ligatures or denuded surfaces have been covered, will require purgation or abstention from purgation for conditions that may happen to present themselves, without reference to the fact that the abdomen has been opened. When such patients have not been dieted either before or after the operation, they may have early spontaneous bowel movements without laxatives or may merely require enemas to assist nature; while others who are accustomed to depend on laxatives may require early purgation for relief. Patients who have been dieted before the operation and in whom the anesthetic has disturbed the stomach will have but little substance in the alimentary canal and may do better without a bowel movement for two or three days.

CONCLUSION

It has been my intention in this communication not to go into an exhaustive discussion of the subject of purgation before and after operation, but merely to call attention to the harm that may be done by employing it in a routine way and to the desirability of individualizing the indications. A routine method may be a good thing for a surgeon or a hospital staff to have on record, not as a method to be followed out, but as one to be modified. It may happen to be just right for some cases, and in others it may require modification only in a few particulars and may thus be of time-saving assistance to the one who formulates the directions for each patient, as well as to the one who has to interpret them and carry them out.

112 South Michigan Avenue.

Malarial Pseudotetanus.—A. Castellani (*Arch. méd. Belg.*, August, 1918) has seen a case in Macedonia and three in tropical countries of malaria simulating tetanus. The patients had a normal temperature, with trismus, opisthotonos and undoubted tetanic spasms. In all the cases the examination of the blood and the happy effects of treatment with quinin proved that they were cases of malaria.

A FILTRABLE POISON PRODUCED BY B. INFLUENZAE (PFEIFFER) *

JULIA T. PARKER
NEW YORK

The clinical course of the present epidemic of influenza has emphasized what appears to be two important points worthy of investigation:

1. The rapidity of onset, suggestive of an overwhelming intoxication, which may be due to a soluble toxin.
2. A marked leukopenia present in most of the cases.

The question of the leukopenia has not, in our opinion, received the attention it deserves, and a succeeding report will deal with that question. The present report deals with the filtrable poison. Although these experiments do not by any means prove that the influenza epidemic is caused by the Pfeiffer bacillus, yet they would seem to indicate this possibility.

Five strains of the influenza bacillus were used in this work. For two of these we are indebted to Dr. Anna Williams; the other three were isolated by us from influenzal pneumonia sputums.

The poison was formed by the growth of *B. influenzae* on several different mediums; the medium, however, with which the most constant results were obtained, was made as follows:

> Veal infusion broth was prepared in the usual way. The required amounts of broth were measured into Ehrlenmeyer flasks and sterilized in the autoclave. The final hydrogen-ion concentration should have a p_H of from 8 to 8.2. To these flasks enough sterile defibrinated rabbit's blood was added to make it 10 per cent. of the whole. The flasks were then heated over a water bath at 75 C. until the blood coagulated and settled on standing. This requires from three to five minutes after this temperature (75 degrees) has been reached.
>
> The flasks were inoculated with one or two slants of *B. influenzae* to every 50 c.c. of medium.

The poison is produced with remarkable speed. We have obtained very toxic filtrates even after only from six to eight hours' incubation. At this time the organisms are growing very rapidly. Most of our work has been done, however, with eighteen or twenty hours' growth. There is no relation between the amount of growth and poison formation.

After incubation the cultures were centrifugalized, and the supernatant fluid was filtered through a Berkefeld candle. The sterile filtrate was then inoculated intravenously into rabbits.

The poison deteriorates very quickly, even when kept in the ice box. For this reason the toxicity of the poison must be tested, and the experiments made on the same day. If 2 c.c. of a poison killed a medium sized rabbit in from one to three hours, we considered it a good poison. Sometimes rabbits died when injected with 1 c.c. of a poison, but this was not the usual result.

When a rabbit is given a lethal dose of the poison, there is an incubation period of about thirty minutes before any symptoms appear. This is followed by increasing weakness, often accompanied by diarrhea. Death usually occurs within three hours, with or without convulsions.

Immunologic tests were carried out as follows: Rabbits were immunized to multiple lethal doses of the poison. The serum of rabbits that have withstood at least four lethal doses of the poison will protect normal animals against lethal inoculation of the poison. An immunity against a poison produced from any one strain will protect against a poison from any other strain. This protection is shown in two different ways:

A. By mixing the lethal dose of the poison in vitro with the serum before inoculation.

B. By giving the serum fifteen minutes before or fifteen minutes after the injection of the poison.

TABLE 1.—EXPERIMENTS IN VITRO ON RABBITS INJECTED WITH MIXTURES OF INFLUENZA POISON AND IMMUNE SERUM

Rabbit	Weight Gm.	Mixture Injected	Remarks
1	1,450	5 c.c. Poison 9 + 2 c.c. Serum 308......	Lived
2	1,530	5 c.c. Poison 9 + 1 c.c. Serum 308......	Lived
3	1,500	5 c.c. Poison 9 + 2 c.c. normal serum..	Dead 1 hr. 10 min.
4	1,530	5 c.c. Poison 9 + 1 c.c. normal serum..	Dead 1 hr. 40 min.
5	1,500	5 c.c. Poison 9..........................	Dead 1 hr. 15 min.
6	1,550	5 c.c. Poison 9..........................	Dead 1 hr. 55 min.

Three average protocols to illustrate these points are given herewith. The mixtures were incubated at 37 C. for half an hour before being injected. Serum 308 was taken from a rabbit which had had eight injections of poison. The rabbit was bled on the eighth day after the last injection. Although 2 c.c. of this poison was the lethal dose in the morning, we used, on account of deterioration, 5 c.c. of it in the afternoon of the same day. This applies also to the protocols given in Tables 2 and 3.

TABLE 2.—EXPERIMENTS ON RABBITS INJECTED WITH INFLUENZA POISON AND INOCULATED WITH IMMUNE SERUM

Rabbit	Weight Gm.	Poison	Serum	Remarks
7	1,360	5 c.c. E	5 c.c. Serum 307............	Died 1 hr. 20 min.
8	1,380	5 c.c. E	10 c.c. Serum 307............	Lived
9	1,400	5 c.c. E	5 c.c. Serum 308............	Lived
10	1,410	5 c.c. E	10 c.c. Serum 308............	Lived
11	1,400	5 c.c. E	5 c.c. normal serum.......	Died 1 hr. 20 min.
12	1,410	5 c.c. E	10 c.c. normal serum.......	Died 23 hr.
13	1,400	5 c.c. E....................................		Died 1 hr. 55 min.
14	1,440	5 c.c. E....................................		Died 2 hr. 7 min.

Rabbits 7, 9 and 11 were inoculated with the specified serum fifteen minutes before the inoculation of the poison. Rabbits 8, 10 and 12 were inoculated with the serum fifteen minutes after the poison. Serum 307 was taken from a rabbit which had had ten injections of poison. The rabbit had been bled on the tenth day after this last injection. Serum 308 was taken from a rabbit which had had ten injections of poison. It had been bled on the fifth day after this last injection.

TABLE 3.—EXPERIMENTS ON RABBITS INJECTED WITH INFLUENZA POISON AND INOCULATED WITH IMMUNE SERUM

Rabbit	Weight Gm.	Poison	Serum	Remarks
15	1,475	5 c.c. 9	10 c.c. Serum 410............	Lived
16	1,450	5 c.c. 9	10 c.c. Serum 410............	Died 3 hr. 45 min.
17	1,415	5 c.c. 9	10 c.c. normal serum.......	Died 1 hr. 35 min.
18	1,475	5 c.c. 9....................................		Died 1 hr. 25 min.
19	1,555	5 c.c. 9....................................		Died 2 hr.

In each case the serum was inoculated fifteen minutes after the poison. Serum 410 was taken from a rabbit which had had eight injections of poison. It had been bled on the seventh day after this last injection.

The following figures, the result of all our experiments, show the value of this serum:

There were seventy animals inoculated with the poison in this series of experiments. Half, that is, thirty-five, were protected with immune serum either in vitro or in vivo. Of these, twenty-seven (77 per cent.) lived. The other thirty-five were controls, and of these only three (7.5 per cent.) lived.

---

* From the Department of Bacteriology, College of Physicians and Surgeons, Columbia University.

SUMMARY

It has been found that the influenza bacillus produces a filtrable poison which is lethal to rabbits. This poison is produced with great rapidity. It also deteriorates very quickly. An immunity can be produced against it. The serum of immune animals appears to be antitoxic both in vitro and in vivo.

RECURRENT RENAL CRISES

GEORGE S. WHITESIDE, M.D.
Lieutenant, U. S. N. R. F.
PORTLAND, ORE.

I desire to call the attention of urologists and particularly of naval surgeons to a syndrome that came under my observation while stationed at the Naval Hospital at Norfolk, Va., in the winter of 1918.

During the winter of 1917-1918, many United States ships were engaged in convoying troop transports by a method that required the convoying ship to be at sea continuously for about three weeks at a time. Many of these ships were second or third class cruisers of about 3,000 to 5,000 tons displacement. It may be remembered that weather conditions were unusually severe over the North Atlantic during that winter. Gales of great violence were frequent, and much of the time the cold was intense. Such ships often encountered weather that made conditions of life on board very trying, with no possibility of making a harbor for protection from the rough seas and extreme cold. Such living conditions affected all members of the crew.

Often, for days together, it was impossible to cook and serve regular hot meals. Such meals as were served were necessarily of a quality that would convey the maximum of nourishment with the minimum of effort and therefore such as left little waste to be eliminated by the intestine. On account of the cold weather, the natural desire to drink water was in abeyance and many did not think of drinking it when they had no craving for it, which resulted in limitation of fluids. The watches on deck, or below, were performed under most trying conditions and were often prolonged beyond the limits set for fair weather navigation. Sleep was much interfered with and was frequently almost impossible. Attention to personal hygiene was out of the question for days at a time. Even attention to regular movements of the bowels or normal frequency of urination was often neglected. These facts are recited because I believe they explain the sort of syndrome of which I saw many instances.

A patient would be sent to the hospital from some ship on such duty, because of recurrent renal colic, sometimes unilateral but more often bilateral. There were recurrent crises of pain simulating such as might be caused by renal stone. Often, constant, dull pain existed between the more acute attacks. The urine was scanty and of high specific gravity. In most cases it contained neither pus nor blood, but a few patients had recurrent renal hemorrhage. Often calcic oxalate or uric acid crystals of small size were numerous in the centrifugalized sediment. Ureteral catheterization in all cases showed the condition to be renal in that any abnormality observed in the evacuated urine before catheterization would be duplicated in that obtained through the renal catheter.

The cystoscopic inspection of the bladder was normal.

In all cases the renal pelves seemed contracted, since from 5 to 10 c.c. of fluid injected was the extreme limit.

The phenolsulphonephthalein test showed almost normal functional ability both as to time and quantity, except in a few cases in which the excretion was slightly delayed. This test was in all cases nearly equal on the two sides.

Pyelogram roentgen-ray plates, taken in every case with 10 per cent. thorium solution, showed no abnormality, except in one case of unilateral colic in which the renal pelvis on the painful side seemed to lie largely below its outlet but was not dilated.

In several cases the injection of 5 or 6 c.c. of thorium solution brought on a renal colic similar to that for which the patient entered the hospital. This was a very striking circumstance.

From consideration of conditions described and facts observed, I believe the colic was induced by decreased renal function over a considerable period of time. Perhaps the condition may have been one of acute renal spasm with or without acute hyperemia, but without gross anatomic or pathologic change. It is interesting that such a condition can be the cause of renal colic.

Treatment of these cases consisted of rest in bed, light diet, increased ingestion of liquids, diuresis, and mild daily purgation. All patients made a gradual and uninterrupted recovery.

One patient had a return of symptoms on going to sea again, even though he was on a larger ship and encountered calm weather.

Owing to the fact that all patients recovered, no pathologic examination of the kidneys was ever made, and therefore the pathology of this condition can only be surmised.

IDIOPATHIC ENURESIS IN ADULTS

HEIMAN CARO, M.D. (Chelsea, Mass.)
Captain, M. C., U. S. Army
FORT SNELLING, MINN.

Nocturnal enuresis in childhood has been thoroughly reviewed in the literature. Concerning the condition in adult life, when no organic neurologic lesion is demonstrable, the literature is meager. Little can be found in most textbooks on neurology when the trouble occurs after the first decade of life; while in the clinical records of large institutions such case histories are without doubt a rarity. Jelliffe and White[1] state that after the third year of life it is an indication of a neurotic disposition, while Osler declares that nocturnal enuresis usually clears up by the end of the first decade.

When, therefore, a group of adult men, in military life, present themselves with this symptom, the conclusion that there is a deliberate attempt to malinger is uppermost in the mind of the observer. But these patients wet their beds or cots consistently. The night attendants in the ward note the dribbling of urine, while the patient sleeps soundly on until morning. In spite of threats, punishments and ridicule, the condition continues unabated, while all such patients show certain constant characteristics. Hence, it becomes inevitable that the conclusion must be forced on the observer that he is dealing with a distinct syndrome, a manifestation of a neuropathic condition.

---

[1] Jelliffe, S. E., and White, W. A.: Diseases of the Nervous System, Philadelphia, Lea & Febiger, 1917.

Military surgeons have described cases of nocturnal enuresis cured by threats of punishment or "special detail" work. In deliberate malingering or slothfulness, these undoubtedly have their effect. But when no simulation exists, the only result is to have the patient redouble his vigilance and to conceal his infirmity by every possible expedient. Then he is returned to duty apparently cured. But with the fatigue of the day's work, he sleeps soundly, does not resort to the various precautionary measures, and awakens in the morning only to find that once more he lies drenched in his own urine. The obnoxious odor, the discoloration of the bedding, etc., call the attention of some officer to his condition, and again he is ordered to the base hospital or to the infirmary. In such cases, the suspicion of malingering cannot be seriously considered. Of course, it is not to be questioned that with the man who reports himself to the regimental surgeon with the usual tale of long treatment at home, deliberate simulation for the purpose of evading further military service may be suspected. But it cannot be denied that he who deliberately lies in his own urine is not only slothful and "good-for-nothing," but a mental defective as well.

In presenting this series of twenty-five case histories of idiopathic enuresis held under observation at the base hospital, Camp McClellan, Ala., it may not be amiss to note at this point certain facts in regard to the care of these men. Every patient was held under observation for at least two weeks; five of the number were admitted to the ward for a second period of observation for the condition. Beyond the protection of the bedding by rubber sheeting, and the restriction of fluid after 5 o'clock in the afternoon, no systematic therapeutic routine was attempted. Bladder irrigations, touching of the posterior urethra with silver nitrate, hexamethylenamin and tincture of belladonna were tried in various cases, but without any amelioration of the condition. In one, a moderate cystitis was present, but the clearing up of this complication was not attended by any change in the severity of the enuresis.

CLINICAL DATA

Age.—These men were from 17 to 38 years of age, the majority being under 25.

Age of Onset.—Twenty-one gave a history of the condition having existed, with short periods of remissions, since early childhood. Of the remaining four, the first patient gave a history of imperative urination since early childhood with nocturnal enuresis for three months prior to admission; the second, following an injury to his back, at the age of 12, but without any evidence of cord irritation at the time of examination, and the third, following a kick in the flank occurring seven months prior to admission (this patient presented evidence of a mild condition of dyspituitarism). In the fourth patient the trouble began at the age of 27 and had existed for eleven years. This patient had a posterior urethral stricture, said by the genito-urinary surgeon not to be venereal in origin. He showed no dribbling of urine during the day. His sister is said to be enuretic.

Family History.—Thirteen patients gave a family history of a similar condition or other neuropathic traits, or of cardiorenal disease. Table 1 shows the incidence of these factors.

Past History.—A history of deep, heavy sleeping was always present, and this was noted repeatedly during the period of observation. Imperative urination during the day was a constant factor. The attempt to retain the bladder contents for even a short period caused considerable pain, and frequently would be attended by incontinence. In several, inability to urinate in the presence of others was noted. Only four of these men gave a history of gonorrheal urethritis, but the enuresis antedated the venereal infection. Periods of remission, never of more than two or three months, were frequent. It was impossible, however, to determine the cause for the return of the enuresis. In none was there obtained a history of epilepsy.

TABLE 1.—FAMILY HISTORY

Case	Father	Mother	Siblings
2	Enuresis until 16	....	Brother until 7
5	Nephritis	Nephritis	
9	....	....	Brother a psychopath
10	*Enuresis until 17* (brother until 20)		
11	Inebriate	Died of cardiac disease	
12	....	Migraine	Sister enuretic
13	Uremia	....	Two brothers enuretic
16	Inebriate		
20	Nephritis	....	Sister enuretic (2)
21	....	....	Brother enuretic
23	....	Cardiac disease	Three brothers enuretic
24	Inebriate	(Brother insane)	Five mental defectives
25	Inebriate	Enuresis	Sister enuretic

Physical Condition.—There were present distinct trends toward the vagotonic constitution: cold skin, cyanotic hands, marked localized perspiration, deep set eyes, acneiform eruptions, increased flow of saliva, and diminution of the faucial reflexes. Only one patient showed any trend toward the sympatheticotonic type. Facial asymmetries of fairly marked degree were noted in thirteen, while deviations from the norm in regard to the hard palate were usually present.

Neurologic examination revealed all the deep tendon reflexes to be very active. The faucial reflexes were diminished in intensity. In none was there any evidence of spina bifida occulta. In only one case was multiple sclerosis suspected, there being slight nystagmoid movements on looking to the right or left, absent abdominal reflexes, and enuresis; but otherwise both history and clinical findings were absolutely negative.

Urologic examination gave no further information. Urinalysis was negative, except in the case of cystitis mentioned. Cystoscopy in eight cases gave normal findings, except that there was constantly present an increased resistance to the catheter at the compressor urethrae muscle. It may be of interest to note here one patient, not included in this series, in whom a marked trabeculation of the bladder with a content, under pressure, of only 60 c.c. was found.

Mental Condition.—Psychometric tests were completed in all cases; the Yerkes-Bridges point scale,[2] with a total of 100 credits, was used. The results are given in Table 2.

The usual defects were found to be in memory span, logical reasoning, judgment and in acuity of insight.

---

[2] Yerkes, R. M.; Bridges, J. W., and Hardwick, Rose S.: A Point Scale for Measuring Mental Ability, Baltimore, Warwick & York, 1915.

All the men had worked steadily at various occupations of a manual character when in civil life. None showed any criminal or other psychopathic trends. But the noticeable feature was their blasé manner, almost amounting to indifference, with which they discussed their ailment. Their attitude can be summed up best in their common answer, "I can't help it."

Summary of Clinical Data.—The factors here presented may be summarized under four headings: (1) a family history of neuropathic or cardiorenal disease; (2) a history of nocturnal enuresis, existing since childhood, with periods of remission, and always accompanied by imperative urination and by deep sleep; (3) a disclosure on physical examination of vagotonic trends, with negative neurologic and urologic findings, (4) all associated with certain borderline defects in mental efficiency.

COMMENT

There is a constant feature in these cases: the noticeable lack of any gross pathologic findings. The cystoscopist has always found normal bladder walls and content, but has noted the increased spasm of the compressor urethrae muscle. Neurologic lesions of the cord were not present.

Any explanation as regards etiology must be presented, then, on an empiric basis. It may be said that the lack of character formation must be considered; but we find that these men are at a period of life when such conditions should be corrected with ease. Instead, our psychotherapeutic measures have failed to be of any value.

Adler[3] believes that this condition can be grouped under the examples of inherited organ inferiority wherein the compensatory overgrowth of other parts of the organ or of other organs has failed to obscure and arrest the defects resulting. Since organ inferiority manifests itself in the most diverse parts and functions of that organ, we have an explanation of our failure to find any gross pathologic conditions. The evidence presented by the cystoscopist would suggest faulty innervation of the bladder and compressor urethrae muscle. The factor of inheritance per se is not as clear in this group of cases as might be wished for. The fact that nine patients gave a family history of enuresis or cardiorenal disease is in support of this view. In addition, the psychiatric examinations reveal certain defects present: a fertile ground for the growth or accentuation of any neurosis. Hence, when this is added to the organ inferiority noted, this condition of enuresis, less noticeable in civilian life, becomes, because of the increased monotony, stress and exhaustion of military life, markedly accentuated.

TABLE 2.—PSYCHOMETRIC TESTS

No. of Cases	Total Credits	Mental Age
4	90 plus	Adult
8	From 75 to 90	From 12 to adult
10	From 65 to 75	From 11 to 12
2	From 56 to 60	From 9 to 10
1	From 40 to 50	From 8 to 9
25		

SUMMARY

1. Nocturnal enuresis in adults is a distinct clinical entity, which does not respond to the routine treatment usually effective in younger individuals.
2. Certain constant clinical findings have been noted.
3. The etiology is obscure. The theory of inherited organ inferiority is applicable.
4. Nocturnal enuresis, idiopathic, is a form of neurosis—a psychophysical defect—wherein the factors of monotony and exhaustion exaggerate the morbid potential present.

DYSTOCIA FROM LARGE BLADDER STONE IMPACTED IN THE PELVIS

C. S. NEER, M.D.
VINITA, OKLA.

From a hasty review of the literature it would appear that serious interference with childbirth by vesical calculi is rather rare. Considering the enormous size which bladder stones sometimes attain, it is surprising that they are not a more common cause of dystocia. That they are not is doubtless due to their comparative rarity in women. Winkle found bladder stone in only one of 10,000 women examined.

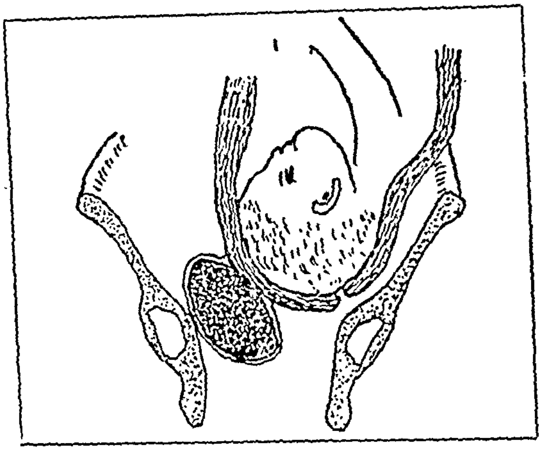

Fig. 1.—Relation of the stone to the head of the fetus.

Pinching of the bladder and anterior vaginal wall with resulting fistula, by stones too small to cause marked obstruction to the descending head, seems to be more common. Thus in Kotschurowa's case referred to by Hirst, labor lasted three days.

> At the end of that time a gangrenous tumor protruded from the vulva, which tumor proved to be the bladder and anterior vaginal wall. The midwife in attendance perforated the tumor with her finger, whereupon a calculus 85 grains in weight was discharged.

G. A. Wagner in 1907 collected forty-six instances from the literature and reported one in which a stone 2 by 4 by 6 cm. became impacted between the symphysis and the head. The nature of the obstruction was not recognized until labor had gone on four days, when it proved to be possible to reduce the stone under general anesthesia and effect delivery. Wagner urges the importance of removing bladder stones before childbirth and considers colpocystotomy with immediate suture of the bladder a very satisfactory procedure.

The diagnosis of bladder stone in the parturient appears to be somewhat difficult. It has been mistaken for pelvic exotosis, cervical fibroid or other pelvic tumor, and according to Hirst, in one case at least, cesarean section was performed on account of this mistake.

dition continues unabated, while all such patients show certain constant characteristics. Hence, it becomes inevitable that the conclusion must be forced on the observer that he is dealing with a distinct syndrome, a manifestation of a neuropathic condition.

Military surgeons have described cases of nocturnal enuresis cured by threats of punishment or "special detail" work. In deliberate malingering or slothfulness, these undoubtedly have their effect. But when no simulation exists, the only result is to have the patient redouble his vigilance and to conceal his infirmity by every possible expedient. Then he is returned to duty apparently cured. But with the fatigue of the day's work, he sleeps soundly, does not resort to the various precautionary measures, and awakens in the morning only to find that once more he lies drenched in his own urine. The obnoxious odor, the discoloration of the bedding, etc., call the attention of some officer to his condition, and again he is ordered to the base hospital or to the infirmary. In such cases, the suspicion of malingering cannot be seriously considered. Of course, it is not to be questioned that with the man who reports himself to the regimental surgeon with the usual tale of long treatment at home, deliberate simulation for the purpose of evading further military service may be suspected. But it cannot be denied that he who deliberately lies in his own urine is not only slothful and "good-for-nothing," but a mental defective as well.

In presenting this series of twenty-five case histories of idiopathic enuresis held under observation at the base hospital, Camp McClellan, Ala., it may not be amiss to note at this point certain facts in regard to the care of these men. Every patient was held under observation for at least two weeks; five of the number were admitted to the ward for a second period of observation for the condition. Beyond the protection of the bedding by rubber sheeting, and the restriction of fluid after 5 o'clock in the afternoon, no systematic therapeutic routine was attempted. Bladder irrigations, touching of the posterior urethra with silver nitrate, hexamethylenamin and tincture of belladonna were tried in various cases, but without any amelioration of the condition. In one, a moderate cystitis was present, but the clearing up of this complication was not attended by any change in the severity of the enuresis.

---

[2] Yerkes, R. M.; Bridges, J. W., and Hardwick, Rose S.: A Point Scale for Measuring Mental Ability, Baltimore, Warwick & York, 1915.

So far as we are able to determine, this makes the eighth case reported in Maryland, two of which occurred in my experience. One of these was reported by Boggs and Guthrie.[3]

Bence-Jones proteinuria is not pathognomonic of myelomatosis, nor is myelomatosis always attended by Bence-Jones proteinuria. It has been found in osteomalacia, in bone injury due to a gunshot wound, in lymphatic leukemia, in myxedema, in carcinomatous bone metastases, and in pleural effusion. There appears to be one point in common, namely, extensive involvement of bone marrow, which suggests the possibility of some relationship in our case of a bone lesion in typhoid with a subsequent development of myelomatosis and Bence-Jones proteinuria

REPORT OF CASE

History.—A farmer, aged 55, from Queen Anne County, Md., was referred by Dr. H. G. Simpers; June 24, 1915. At the age of 35 he had pneumonia, and at 50, typhoid fever. He also gave an indefinite history of malaria; otherwise his health had been good. Since the attack of typhoid fever, five years before, he had suffered intermittently from substernal pains. These pains at first lasted several days; they gradually increased in duration to a week or two, and the last attack persisted for three weeks. He was singularly free in summer, but always worse in the spring and fall. He described the pain as burning in character and radiating from beneath the sternum to both shoulders; there was no diurnal or postural influence. However, it was aggravated by the slightest bodily movements. Associated with the pain were dyspnea and a hacking cough without expectoration. There was no dysphagia and no history of gastro-intestinal or genito-urinary disturbances. He had lost about 26 pounds in weight and was progressively growing weaker.

Physical Examination.—The patient was pale, thin and emaciated, and weighed 132 pounds. The eyes were sunken, the lids pigmented, the conjunctivae injected, the sclerae were icteroid, the pupils were even, reacting sluggishly, and arcus senilis was marked. Tophi were present in both ears. The patient suffered with a severe form of pyorrhea alveolaris, a mild chronic pharyngitis, and fissures of the tongue. The cervical lymph glands were slightly enlarged and the thyroid was normal. There were no abnormal pulsations in the neck. The hands were moist, cold and tremulous. Fibrillation was noticed in the muscles of both arms. The brachials were prominent, tortuous and sclerosed, and pulsated forcibly. Atheromatous patches were found in the radials. The pulse was regular, the rate being 84 per minute. The chest was elongated and irregularly flattened. There was a definite swelling of the sternal end of the right clavicle, due to thickening of the bone, and a similar swelling, although less prominent, at the sternal end of the left clavicle. At the junction of the second left rib and sternum there was a circumscribed swelling, fairly regular in outline, measuring about 5 cm. in diameter. These swellings presented rather smooth, even surfaces; they were firm, and not tender to pressure. There was no evidence of crepitation or fluctuation. Superficial veins were large and prominent over the upper anterior thoracic zone, and were especially pronounced over the upper sternal region.

A fluttering pulsation with marked systolic retraction was observed in the epigastrium. There was also systolic retraction in the second left intercostal space and a well defined Broadbent's sign. There was no circumscribed apex impulse, but instead a slight heaving of the chest wall over the entire precordia. Heart dulness was increased to the left. At the apex (sitting) loud to and fro blowing systolic and presystolic murmurs were heard, accompanied by a thrill. These murmurs were distinctly audible posteriorly at the angle of the scapula. In the recumbent posture they were almost inaudible. The aortic sounds were feeble, the pulmonic clear. In both apexes of the lungs breath sounds were impaired and numerous scattered râles were heard below both clavicles. Visceral examination of the abdomen was negative except for a palpable kidney on the right side. Roentgenologically, no definite bone changes were demonstrated; but plates showed enlargement of the heart and numerous large, calcified mediastinal glands, especially on the right side.

The urine was free from serum albumin, but contained a protein that strongly suggested Bence-Jones in regard to its behavior with the heat, nitric acid and acetic acid and potassium ferrocyanid tests. The amount of urine obtained was insufficient to confirm Bence-Jones protein by other tests. A summary diagnosis was made of chronic gout, arteriosclerosis, pyorrhea alveolaris, chronic endocarditis with adhesive pericarditis, and multiple myeloma.

Second Admission.—The patient was not seen again until Nov. 24, 1915, when he was admitted to the Mercy Hospital suffering with acute lobar pneumonia involving the right lung, in addition to his chronic affections. The tumor on the sternum was found to be greatly increased in size. It was soft and somewhat tender to pressure. There was no fluctuation or crepitation. By manipulation or deep breathing a pathologic fracture at the junction of the manubrium and glandiolus could easily be recognized. The enlargement of the sternal ends of the clavicles had increased in size, but their consistency was not altered. Additional nodular thickenings were noticed on the third and fourth ribs of the right side in the mammillary line.

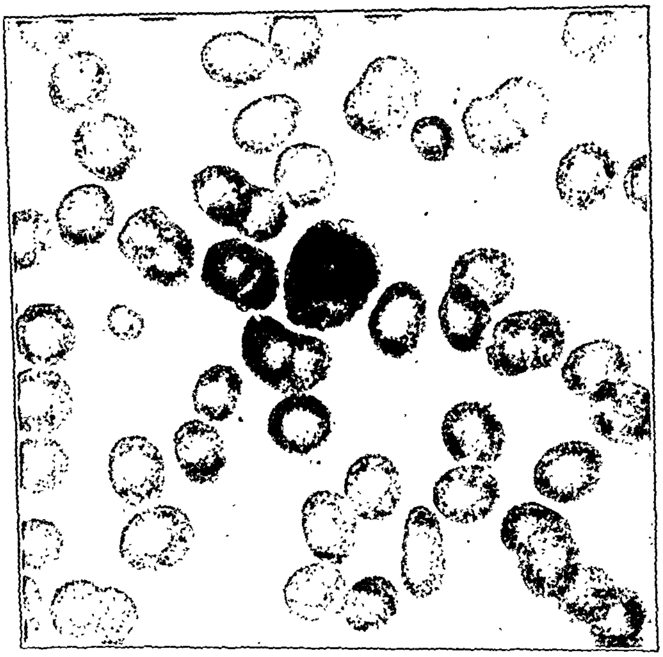

Fig. 2.—Blood smear showing plasma cell with transversely placed nucleus and nucleolus.

Urinalysis.—Dr. Judd, who made a special study of the urine, made the following report: Between 54 C. and 56 C. a white, flocculent precipitate was thrown down, which on boiling almost (but not entirely) disappeared; on cooling from 56 C. this cleared up only partially. When filtered at from 56 C. to 70 C. a small portion at 60, 65 and 70 C. was recoagulated on further heating, showing that not all the albumin was precipitated at one time. When the precipitate up to 70 C. was collected by filtration and heated to 100 C. and again filtered, the clear filtrate became distinctly cloudy on cooling. Nitric acid caused a precipitate that persisted after shaking. The rather atypical findings were attributed to the absence of chlorids dependent on pneumonia. When a strong sodium chlorid solution was added to antiacidified urine, the precipitate was obtainable. Before salting, a definite albumin, as well as albumose, was present. By lessening the degree of salting out the albumin also was precipitated at 100 C., showing the dual presence of albumin and albumose. Microscopically the urine showed numerous fine and coarsely granular casts.

---

[3] Boggs and Guthrie: Am. J. M. Sc. **164**: 803, 1912.

Blood Examination.—The Wassermann test was negative. Cultures revealed a pneumococcus septicemia. The red count was 2,200,000; the white count, 8,800. Differential count revealed: small lymphocytes, 14.3 per cent.; large lymphocytes, 4.3; neutrophils, 73.3; eosinophils, 0.3; neutrophil myelocytes, 1.3; bone marrow plasma cells, 6.6; normoblasts, 1 in 300.

Before the death of the patient the cells here regarded as plasma cells were enumerated as irritation cells. It was not until after necropsy that these cells were identified as similar to those found in the bone marrow.

PATHOLOGIC STUDY, BY DR. MC CLEARY

Necropsy.—Thorax: The sternal end of the right clavicle was much enlarged, and the entire bone was easily crushed. The osseous tissue was much thinned and the marrow a yellowish gray, in areas resembling putty. The sternal end of the first rib was similarly involved. The sternum, from the second to the fourth rib, was thickened and softened and was easily incised with a knife. There was a pathologic fracture of the manubrium. The costal cartilages were nodular.

The right pleura was adherent to the pericardial sac, and both pleurae were adherent to the chest wall. The right lung was entirely consolidated, and microscopically showed lobar pneumonia in a stage of transition from red to gray hepatization. The left lung was edematous, with hypostatic congestion at the base.

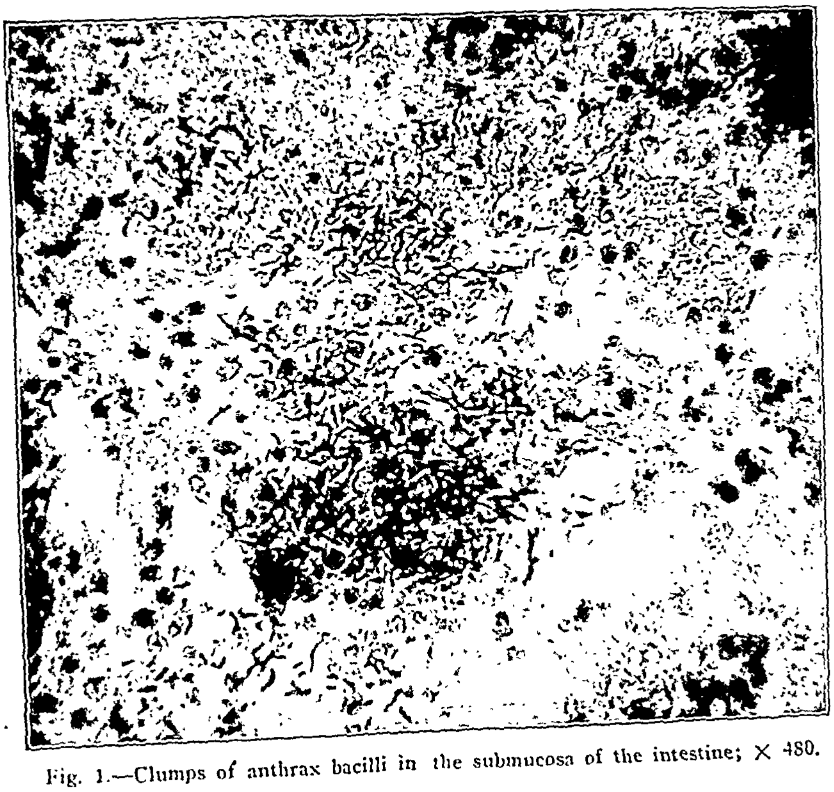

Fig. 1.—Clumps of anthrax bacilli in the submucosa of the intestine; × 480.

The heart weighed 350 gm.; the valves and coronary arteries were normal. There were no atheromatous areas in the aorta.

Abdominal Cavity: The kidneys and liver alone showed any pathologic process. The kidneys showed the changes usually described as chronic diffuse nephritis, tubular degeneration, numerous casts beginning connective tissue increase, and a slight degree of arteriosclerosis.

Liver: A few nodules the size of a pinhead were found. These apparently were minute gummas. The sinusoids of the liver contained the same cells found in the blood and bone marrow.

No head section was allowed. A careful search failed to reveal any involvement of the skeleton except those parts mentioned—ribs, sternum and clavicle—and no extraskeletal masses could be found.

Smears were made from the affected bones, and the tissue was hardened for sections. The smears were stained with Wright's stain and by indophenol blue to determine if the oxydase reaction could be obtained. After Wright's stain, the striking feature of the slide was the presence, in an overwhelming majority, of cells of an oval shape with an eccentric nucleus placed transversely to the long axis of the cell. The cells contained a distinct nucleolus. The cytoplasm was nongranular and faintly basophilic. The nuclear membrane was distinct, and the chromatin had a definite mural arrangement. The other cells present were those common to the marrow of this tissue. These oval cells with the characteristically placed nucleus and with a nucleolus were usually regarded as bone marrow plasma cells. Measurement of a large number gave 11.3 microns as the average longest diameter of the cells and 7 microns of the nucleus.

When subjected to the indophenol blue synthesis after formaldehyd fixation, these oval cells showed the presence of the oxydase granules. This fact would place this myeloma in the myeloid group, even though the morphology of the cell was that of the so-called plasma cell.

It is to be regretted that all of the blood smears obtained were stained by Wright's or by Pappenheim's stain and that we were unable to use indophenol blue on the cells of the blood that were morphologically identical with those found in the growths. The presence of the tumor cells in such a large percentage in the circulating blood is unique.

ANTHRAX ENTERITIS

THE MORBID ANATOMY AND HISTOLOGY OF TWO CASES AT CAMP DODGE, IOWA

ARTHUR S. BRUMBAUGH, M.D. (Altoona, Pa.)
Captain, M. C., U. S. Army
CAMP DODGE, DES MOINES, IOWA

REPORT OF CASES

Case 1.—*History.*—A negro private, aged 28, complained of pain in the abdomen five days before entering the hospital. His temperature was normal, and as he did not seem very ill, he was allowed to remain in quarters. Four days later the regimental surgeon found him to be quite ill, with a temperature of 102 F. and great abdominal distention and distress. A tentative diagnosis of intestinal obstruction was made. On arriving at the hospital he was assisted from the ambulance to the receiving ward, seated himself on a chair, and ten minutes later expired. A lesion on his face, later found to be a malignant pustule, had evidently given little discomfort, as the attention of the attending surgeon was not called to it or its character suspected.

Necropsy.—This was held four hours after death. The subject was large and well built. In front of the right ear on the bearded portion of the face there was a dark reddish circular, elevated area 3 cm. in diameter, having a depressed center covered with a firmly attached, brownish scab. The lesion was but slightly indurated, moved freely with the skin over the subjacent tissue, and contrasted but slightly with the black, normal skin. The abdomen was distended.

In the peritoneal cavity were found 4.5 liters (4¾ quarts) of thin, serous, straw colored, slightly cloudy fluid. The peritoneum was hyperemic, the vessels being congested and visible as a network under the serosa. The small intestine was found to be mottled with discrete, purplish red, thickened areas varying in size from 1 to 6 cm. in longest diameter, and oval, having the long axis parallel with the course of the intestine. Over some of these patches the peritoneum was roughened and mottled with grayish exudate. The mesenteric lymph nodes were enlarged and purplish.

When the stomach was opened the rugae were found to be quite prominent. The gastric mucosa was covered with gray, blood-streaked mucus. In the duodenum 3 cm. from the pylorus was found an oval, elevated ulcer covered with black coagulum, the margin of which was elevated, and the center depressed and grayish.

In the intestine, Peyer's patches and the solitary follicles were found to be enlarged, dark red and edematous, with elevated, irregular margins and a slightly necrotic, bile stained surface. The lesions were irregularly oval and of variable size up to 8 cm. in long diameter, appearing somewhat larger on the mucous than on the serous surface. The inflammatory process extended to the surrounding tissue, which was edematous and infiltrated with blood, and the areas involved were therefore much larger than the anatomic boundaries of the lymphatic tissue. The lesions were found throughout the length of the small intestine. In the jejunum the valvulae conniventes in the vicinity of the lesions were edematous and projected as prominent, rounded, translucent, grayish ridges. Some of them were reddish and had some resemblance to small cherries. Occasional Peyer's patches were surrounded with such formations.

The bronchopulmonary lymph node measured 5 by 3.5 cm. It was partially calcified and contained large pockets of friable caseous material. The tracheal mucosa was reddened and bathed with bloody mucus. A few quiescent tubercles were found in the apex of the left lung and in the lower lobe of the right lung. The heart appeared unchanged. The spleen weighed 179 gm. and was soft and slate colored, and on section the pulp scraped off easily. The malpighian corpuscles appeared as large gray bodies on a dark red background. A small tubercle was found just beneath the capsule. The kidneys showed the appearance of acute nephritis, being very dark red and mottled with minute hemorrhages.

Anatomic Diagnosis.—This was:

1. Anthrax pustule on face.
2. Tuberculous bronchopulmonary lymphadenitis.
3. Solitary tubercles in upper left and lower right lobes of the lungs.
4. Acute nephritis.
5. Acute splenitis.
6. Anthrax enteritis.
7. Acute mesenteric lymphadenitis.
8. Seropurulent peritonitis.

Bacteriologic Findings.—Anthrax bacilli were found in a smear from the face lesion, in the peritoneal exudate, in bile from the gallbladder and in the heart's blood.

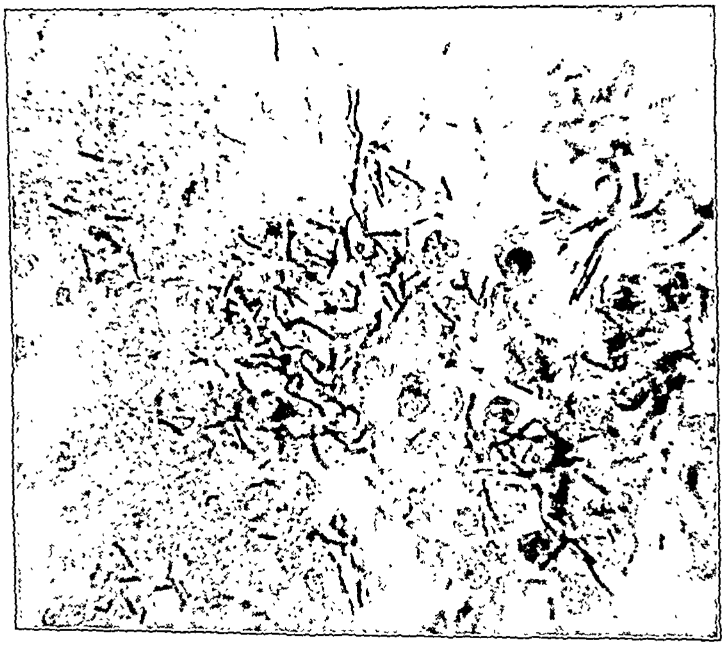

Fig. 2.—Morphology of the anthrax bacillus in the intestinal wall; × 1,000.

Histologic Findings.—Section of Intestinal Lesion: There was an extensive leukocytic infiltration of the entire thickness of the intestinal wall, but the lymphoid tissue was especially involved. Certain areas were very edematous, the cells standing widely apart. Hemorrhagic extravasation was abundant throughout the lesion, but was most marked in a zone just beneath the serous coat and the adjacent portion of the muscular layer. Anthrax bacilli appeared as large gram-positive rods and filaments occurring in enormous numbers in the submucosa and in smaller numbers throughout the section. The large masses of bacilli could be readily seen with the low magnification (× 100).

Section of Mesenteric Lymph Node: Edema and hemorrhage were present, and anthrax bacilli were found scattered through the tissue, but appear to have a special affinity for the germ centers, many of these oval areas being thickly packed with the rods.

Section from Kidney: The cortical tubular epithelium was cloudy and granular. Numerous interstitial hemorrhages were found between the tubules. The glomeruli also were hemorrhagic.

Case 2.—*History.*—A white private, aged 29, noticed a pimple at the angle of his jaw which he picked with his finger and two days later cut while shaving, after which it swelled rapidly. On his entering the hospital next day there was found a lesion 3 cm. in diameter in the center of which was a small ulcer discharging bloody pus, which was found to contain anthrax bacilli. Local improvement was obtained by the use of local antisepsis and the intravenous administration of horse serum, but on the third day after admission he developed epistaxis, nausea, vomiting and abdominal pain, and died on the following day.

Necropsy.—This was held four hours after death. The subject was well nourished. On the right side of the neck below the angle of the jaw was found an indurated area 2 cm. in diameter covered with a dark greenish scab. Behind the right ear was a large edematous protuberance.

The peritoneal cavity contained 600 c.c. of opalescent seropurulent fluid. The serosa of the cecum, ascending and transverse colon was very edematous, translucent, yellowish gray, and thickened to a depth of 15 mm. in certain places. The ascending and transverse mesocolon were also very edematous, and on section exuded clear serum. The mesenteric lymph glands, especially those near the head of the pancreas, were enlarged and purplish. The entire mesentery was very edematous. The duodenum sagged downward from the head of the pancreas toward the promontory of the sacrum 8 cm. below its normal position. Shining through the peritoneal coat of the intestine could be seen numerous oval, purplish patches varying from 1 to 5 cm. in long diameter. They appeared most numerous in the jejunum, but could be found throughout the small intestine.

The esophagus was unchanged. In the stomach were found eight purplish, acuminate, swollen nodules averaging 8 mm. in diameter in the mucosa, some on the rugae and others between them, sharply demarcated from the normal gray membrane. The first and second portions of the duodenum were markedly dilated, the walls at this point being purplish, thickened, edematous and studded with a number of irregularly shaped, elevated nodules varying in size from 5 to 25 mm. in diameter, in some places becoming confluent. The central portion of the surface of the lesions was covered with necrotic membrane. The upper portion of the jejunum was markedly involved, the valvulae conniventes being very edematous, grayish and translucent. Scattered over the mucous membrane were numerous purple elevated nodules averaging 8 mm. in diameter, surmounted by yellowish necrotic tissue. Most of these nodules were found to be enormously swollen solitary lymph follicles, although some of the lesions occurred independently of the lymph tissue. These small lesions were found along the course of the intestine down into the ileum, where it was found that Peyer's patches were outlined by purplish thickened areas which could be seen especially well shining through the serous coat, the overlying vessels of which were hyperemic and formed a distinct network. On the mucous surface, Peyer's patches were less distinct, although there was some thickening, and a dull purple marked their location. In the lower end of the ileum as the cecum was approached, the lesions became fainter, less thick and farther apart. No discrete lesions were found in the mucosa of the cecum or colon, but their walls were very edematous. The spleen weighed 209 gm., and the pulp was soft and diffluent.

Anatomic Diagnosis.—This was:

1. Malignant pustule on face.
2. Acute splenic tumor.
3. Anthrax enteritis.
4. Seropurulent peritonitis.

Bacteriologic Findings.—Anthrax bacilli were found in the heart's blood and peritoneal exudate.

Histologic Findings.—Sections of the intestinal lesions and mesenteric lymph nodes were similar to those of Case 1.

Section of the spleen, stained by the Gram-Weigert method, revealed anthrax bacilli scattered through the pulp.

SYNOPSIS

These two cases present the following salient features:

1. Marked involvement of the first portion of the duodenum.
2. Selective action of the infection for the lymphatic tissue of the intestine, somewhat analogous to typhoid fever.
3. The accumulation of the bacilli in the germ centers of the involved lymph nodes.
4. Great intensity of the inflammatory process, with associated edema and hemorrhagic extravasation.
5. Penetration of the entire thickness of the intestine and invasion of the peritoneum, producing seropurulent peritonitis.
6. The rapidly fatal course of the affection.

The probable mode of transmission of the infection to the intestine was by contamination of the food by the fingers infected by the scratching of the initial lesion induced by the intense itching that usually accompanies the process. The sterilization of the patient's hands before meals or the wearing of rubber gloves is suggested as a useful measure in the treatment of anthrax to prevent the fatal intestinal involvement.

THE EXPERT AND THE ISSUE

SANGER BROWN, M.D.
CHICAGO

Unhappily it not infrequently transpires that the physician, when acting as expert in medicolegal cases, leaves the witness stand painfully conscious of having failed, perhaps ignominiously, in his attempt to lay his opinion fairly before the court. In this event, he and the attorney who engaged his services alike suffer from a sense of disappointment and discomfiture.

In a brief discussion of medicolegal cases in which either insanity is set up as a defense in a criminal charge or it is sought to prove that insanity, apoplexy or some other disease has destroyed testamentary capacity, it is my purpose to offer hints or suggestions which, if accepted, might in my opinion measurably minimize the liability to such a distressing experience.

By way of introduction to a given case, I hold that it is of cardinal importance that the attorneys who seek his assistance should submit to the expert all facts and information which they have reckoned on as possessing medical significance in support of the contention which they wish to establish. This material should then be thoroughly analyzed and discussed, and a definite understanding reached between lawyer and physician as to the position the latter is willing to attempt to maintain on the witness stand, taking care especially to anticipate what answers might have to be given to questions put in cross-examination; for although a candid expression of his opinion at this initial stage may terminate the expert's further connection with the case, superficial or hasty performance of this preparatory work only too surely invites disaster when the medical witness enters the box.

THE INSANITY PLEA TO A CRIMINAL CHARGE

Those cases may first be considered in which it is claimed for the defendant that he was insane when he committed the particular criminal act with which he stands charged.

The wide variation between the services demanded of the medical expert in the trial of these cases and those required of the clinician when engaged in the examination of a patient should be kept prominently in view throughout. According to my observation, this distinction, if not altogether ignored, rarely receives the recognition which its importance merits.

In the trial of the cases under consideration, the essential question is: Was the defendant insane when a specified act was committed? The definition, "Insanity is a disease affecting the brain so as to cause a change in feeling, thinking and acting which disqualifies the individual for supporting the ordinary relations of life," is one which in practice has much to commend it. Having adopted it as working formula, the alienist should insist on the importance of limiting the inquiry to the discovery of evidence tending to prove that the designated change had or had not taken place. In this sort of investigation it may be held that there is only one insanity, and that it is not material to attempt to determine into what particular group or class its predominating manifestations would properly place it. Thus much unprofitable wrangling over the vexed and illusory problem of classification may be avoided; the obligation to undertake the baffling and hopeless task of elaborating and erecting a clinical entity that shall correspond, satisfactorily, to such terms as dementia praecox, paranoia, manic-depressive insanity, pyromania, or what not, disappears. Similarly it is not material to prove that the defendant's family is or is not tainted or that he himself has or has not suffered from any disease, injury or stress, commonly recognized as an exciting cause of insanity. And in the same category may be placed as immaterial such subjects as pathology, prognosis and treatment.

To obscure or shift the real issue would appear to be a well recognized measure of legal strategy. With a textbook before him, the opposing counsel may attempt to draw the expert into a discussion of subjects of more or less importance clinically and in regard to which the opinions of students are more or less at variance, but which are not material to the question before the court. If by any crafty device the witness can be maneuvered into foreign and at the same time highly speculative and controversial territory, and there drawn into a discussion, the opposing counsel will attempt to maintain in argument that answers conceding that certain topics are open to debate are admissions that the expert is in doubt regarding the real question at issue. As a matter of course, assuming that proper preparation has been made, tactics of this nature will be promptly and duly opposed.

As instances of attempting to shift the issue, two cases may be cited. In the first, in order to secure a verdict for their client, the counsel rested their hopes on showing that he was subject to predisposing, and in the second to exciting, causes of insanity.

Case 1.—A working man lost all his hard earned savings through having made, as he supposed, a joint investment with a man in whose ability and integrity he reposed confidence. For reasons good and sufficient from his point of view he discovered that he had been heartlessly betrayed; and under circumstances of a supremely exasperating nature, he killed the man who he believed had compassed his ruin. A plea of insanity was set up in his defense, and his attorneys occupied several days, indeed by far the major part of the whole time taken by them in the examination of witnesses, in attempting to prove the importance of heredity as an etiologic factor in insanity, and that the defendant's grandfather was insane.

Case 2.—A woman, actuated by hatred and revenge, cunningly contrived and executed a plan involving arson and murder. In conformity with the plea of insanity made in her defense, for several months prior to her trial she was confined in a hospital for the insane, where the uterus and ovaries were removed. At the subsequent hearing, numerous physicians testified that they had examined the exsected organs, found them obviously diseased, and that their condition constituted convincing evidence of the insanity of the woman from whom they had been taken.

Obviously, the obligation to prove that a given individual was insane at a designated time cannot be fairly met by demonstrating ever so conclusively that he was subject to any or all recognized causes. And conversely, neither is evidence intended to prove the absence of cause material when seeking to establish sanity.

As already stated, the line of inquiry should be directed with a purpose of discovering such a change in the individual as will warrant a diagnosis of insanity. This implies gaining an intimate acquaintance with the personal history from early childhood if possible; for the expert must estimate the departure of questionable conduct from that normal to the individual by comparing it with his usual personal characteristics; and this, of course, implies a searching scrutiny of the circumstances or setting of the debatable act or acts.

Lawyers are prone to be governed by the popular fallacy that it is possible to construct a more or less definite[1] mental norm embracing a specified range of moral, emotional and intellectual reaction which may serve as a general standard of comparison, for the purpose of determining the significance of particular conduct as indicating the sanity or insanity of the person who has exhibited it. Thus, failing to recognize that every individual has a mental norm peculiar to himself with which alone any of his questionable acts must be compared, the counsel feels impatient when the expert insists that the previous personal history be fully and minutely developed. He wishes to proceed directly to the task of demonstrating how widely the conduct under investigation is at variance with his conception of a general norm as described above. He is eager to produce witnesses of fact to prove that certain grossly irregular and unconventional acts were committed, and he believes that this proof alone should afford a sufficient foundation for the basis of an expert opinion. Or if, on the other hand, his purpose is to prove the sanity of his client, he attempts to expand the dimensions of what he assumes should be accepted as a standard mental norm so that it will easily include all deportment under scrutiny, and to this end he usually quotes the published eccentricities of various historical characters who, if insane, had probably never been publicly so adjudicated. When, in prosecuting this line of contention, counsel asks if the cited practices or opinions denoted the insanity of the person to whom they were attributed, the expert witness may logically reply that such a question could not be fairly answered unless a very full and minute record of the individual's personal history was available.

Though the suit was a civil action, the following case may be briefly cited to illustrate my contention that, in order to establish a charge of insanity, the cardinal issue is to prove that the person in question has undergone certain changes in feeling, thinking and acting:

Case 3.—The widow and surviving children of a gentleman who had risen from obscurity to a position of national prominence in industrial and financial circles attacked his will, charging insanity. Perodic debauches, when he would consort exclusively for perhaps a week or more with disreputable people of both sexes exercising no restraint in matters of sexual or alcoholic indulgence, were relied on by the prosecution as sufficient to prove the contention. The testimony of the widow who had married the testator when both were quite young, suffering under a keen sense of lifelong neglect and humiliation, was voluble, minute and convincing when describing the reprehensible practices of her deceased consort; among other statements she testified that she had conducted very searching investigations which had demonstrated conclusively that he had gone on these "high sprees" throughout the whole course of their married life, and even prior to their marriage. Since impairment of business sagacity or any other evidence of derangement of the mental faculties was not claimed, in order to win his case, it was necessary for the counsel for the defense merely to lead the witness on cross-examination to reiterate her direct testimony, which showed conclusively that the periods of moral laxity that were being offered as evidence of the testator's insanity were nothing more than instances of the practice of a lifelong habit.

The medical expert should be careful not to permit the developing fascinations which not infrequently appear in the progress of a case to induce him to invade the proper province of the lawyer and attempt to direct how his special contribution shall be brought into requisition during the course of the trial. When he has critically weighed and sifted all available evidence with reference to its medical significance, and explained clearly to the counsel what position he will undertake to maintain or direct, as well as what he will be obliged to admit on cross-examination, the expert may fairly claim to have discharged his responsibility. For on reflection it seems altogether probable that in the examination of witnesses and in argument, an experienced and well qualified barrister is much better able to judge just how such information as the medical witness may impart to him can be used to advantage than would the expert himself.

In legal practice, many formalities have to be observed which appear superfluous to the layman; but investigation will usually disclose the fact that such arbitrary and minute methods of procedure are essential to the preservation of some basic principle of law or practice; and perhaps it is only fair to allow that some of the proposed amendments submitted by members of our profession to improve methods long in vogue in the conduct of medicolegal cases clearly demonstrate that their proponents have not duly recognized the importance of yielding to these fundamentals. The expert is naturally impatient to have the facts and opinions that he is prepared to present submitted frankly and directly to the jury; the trial lawyer, on the other hand, in the interest of his client must take into account a variety of considerations in the introduction of evidence. In selecting the jury, the personal characteristics of his experts as well as the testimony he expects from them should, no doubt, strongly influence his choice; for, obviously, before going into action a prudent combatant would set his target with due reference to the range of his ordnance.

---

[1] Mental Norm is proposed as a convenient term by which to designate normal emotional, moral and intellectual reaction.

Bacteriologic Findings.—Anthrax bacilli were found in the heart's blood and peritoneal exudate.

Histologic Findings.—Sections of the intestinal lesions and mesenteric lymph nodes were similar to those of Case 1.

Section of the spleen, stained by the Gram-Weigert method, revealed anthrax bacilli scattered through the pulp.

SYNOPSIS

These two cases present the following salient features:

1. Marked involvement of the first portion of the duodenum.
2. Selective action of the infection for the lymphatic tissue of the intestine, somewhat analogous to typhoid fever.
3. The accumulation of the bacilli in the germ centers of the involved lymph nodes.

THE EXPERT AND THE ISSUE

SANGER BROWN, M.D.

CHICAGO

Unhappily it not infrequently transpires that the physician, when acting as expert in medicolegal cases, leaves the witness stand painfully conscious of having failed, perhaps ignominiously, in his attempt to lay his opinion fairly before the court. In this event, he and the attorney who engaged his services alike suffer from a sense of disappointment and discomfiture.

In a brief discussion of medicolegal cases in which either insanity is set up as a defense in a criminal charge or it is sought to prove that insanity, apoplexy or some other disease has destroyed testamentary capacity, it is my purpose to offer hints or suggestions which, if accepted, might in my opinion measurably minimize the liability to such a distressing experience.

By way of introduction to a given case, I hold that it is of cardinal importance that the attorneys who seek his assistance should submit to the expert all facts and information which they have reckoned on as possessing medical significance in support of the contention which they wish to establish. This material should then be thoroughly analyzed and discussed, and a definite understanding reached between lawyer and physician as to the position the latter is willing to attempt to maintain on the witness stand, taking care especially to anticipate what answers might have to be given to questions put in cross-examination; for although a candid expression of his opinion at this initial stage may terminate the expert's further connection with the case, superficial or hasty performance of this preparatory work only too surely invites disaster when the medical witness enters the box.

THE INSANITY PLEA TO A CRIMINAL CHARGE

Those cases may first be considered in which it is claimed for the defendant that he was insane when he committed the particular criminal act with which he stands charged.

The wide variation between the services demanded of the medical expert in the trial of these cases and those required of the clinician when engaged in the examination of a patient should be kept prominently in view throughout. According to my observation, this distinction, if not altogether ignored, rarely receives the recognition which its importance merits.

In the trial of the cases under consideration, the essential question is: Was the defendant insane when a specified act was committed? The definition, "Insanity is a disease affecting the brain so as to cause a change in feeling, thinking and acting which disqualifies the individual for supporting the ordinary *relations of life*," is one which in practice has much to commend it. Having adopted it as working formula, the alienist should insist on the importance of *limiting the inquiry to the discovery* of evidence tending to prove that the designated change had or had not taken place. In this sort of investigation it may be held that there is only one insanity, and that it is not material to attempt to determine into what particular group or class its predominating manifestations would properly place it. Thus much unprofitable wrangling over the vexed and illusory problem of classification may be avoided; the obligation to undertake the baffling and hopeless task of elaborating and erecting a clinical entity that shall correspond, satisfactorily, to such terms as dementia praecox, paranoia, manic-depressive insanity, pyromania, or what not, disappears. Similarly it is not material to prove that the defendant's family is or is not tainted or that he himself has or has not suffered from any disease, injury or stress, commonly recognized as an exciting cause of insanity. And in the same category may be placed as immaterial such subjects as pathology, prognosis and treatment.

To obscure or shift the real issue would appear to be a well recognized measure of legal strategy. With a textbook before him, the opposing counsel may attempt to draw the expert into a discussion of subjects of more or less importance clinically and in regard to which the opinions of students are more or less at variance, but which are not material to the question before the court. If by any crafty device the witness can be maneuvered into foreign and at the same time highly speculative and controversial territory, and there drawn into a discussion, the opposing counsel will attempt to maintain in argument that answers conceding that certain topics are open to debate are admissions that the expert is in doubt regarding the real question at issue. As a matter of course, assuming that proper preparation has been made, tactics of this nature will be promptly and duly opposed.

As instances of attempting to shift the issue, two cases may be cited. In the first, in order to secure a verdict for their client, the counsel rested their hopes on showing that he was subject to predisposing, and in the second to exciting, causes of insanity.

Case 1.—A working man lost all his hard earned savings through having made, as he supposed, a joint investment with a man in whose ability and integrity he reposed confidence. For reasons good and sufficient from his point of view he discovered that he had been heartlessly betrayed; and under circumstances of a supremely exasperating nature, he killed the man who he believed had compassed his ruin. A plea of

At that time the patient complained of no pain, and was lying quietly in bed. His right lower leg was tremendously swollen, tense, bluish-black, and with several blebs, varying in size from 1 to 6 cm. in diameter, and filled with dark reddish fluid. The foot was swollen and blue, and the toes were also somewhat swollen, blue and cold. Above the knee the leg was swollen, the color being a reddish purple, gradually fading into a dull reddish to about the junction of the middle and lower thirds of the thigh, where a sharp raised irregular line of demarkation was present. The tissues of the calf of the leg were tense, and crepitated on pressure. There was no evidence of any wound. The patient's appearance at that time was one of profound toxemia, with sunken eyes and anxious expression, the temperature being 103, and the pulse 120 and somewhat thready. A mere glance at the part was sufficient to make a diagnosis of gas bacillus infection, and the patient was at once transferred to the surgical department, where multiple linear incisions were made in the calf of the leg and in the thigh. As soon as the tissues of the calf were cut, the part burst open, exuding frothy, reddish fluid with a very foul odor. The tissues were completely destroyed, the muscles having a dark necrotic appearance. The patient died that afternoon. The body was at once removed to the morgue, as much blood as possible was drained out, and 3 liters of embalming fluid were at once injected. In spite of this the tissues swelled and the body became discolored, presenting a most repulsive appearance. Postmortem incisions showed complete necrosis of the muscles of the calf down to the bone. The bacteriologic examination of the contents of the vesicles and of the bloody, foamy fluid in the incision, and smears of pieces of necrotic muscles showed numerous typical short, thick, encapsulated bacilli. Inoculations were made anaerobically into boiled agar, and typical pure culture of *B. aerogenes-capsulatus* was obtained showing also gas formation in the medium.

COMMENT

This case presents one of the fearful accidents which happen once in a great while and for which no one on the staff of the hospital can be blamed. From the same tube containing the tablets of caffein sodiobenzoate, other hypodermic injections were given to other patients. All the tablets in this particular tube had been used and the tube had been thrown away before the diagnosis was made, so that no opportunity was given to examine the contents of the tube for the presence of the gas bacillus.

The question naturally arises at once, Where did this infection originate? On going over the history carefully, it seems to us that the only explanation possible is that this man carried on his person spores of the gas bacillus. He came from a small town in Georgia and was a blacksmith by occupation. Naturally a man from such a place, in such work, was dealing constantly with animals, particularly horses, and the very nature of his work exposed him to contamination from manure on his lower legs. He had had on both arms a number of hypodermic injections, with no resulting infection. However, the very first injection under all aseptic precautions, in the calf of his leg, at once gave rise to a virulent gas bacillus infection. There is no doubt in our minds that this man's occupation was the indirect cause of his death. It emphasizes anew the well known fact that too little attention is paid on the part of physicians and nurses to the occupation of the patient. Had it been realized that this man was a blacksmith, both the ward surgeon and the nurse might have hesitated to inject anything into the lower leg because of the rare chance of inducing some virulent infection with an organism which was present on the skin, as an incident to his occupation.

INFLUENZA AND INFLUENZAL PNEUMONIA AT FORT RILEY, KANSAS

FROM SEPT. 15 TO NOV. 1, 1918

WILLARD J. STONE, M.D. (TOLEDO, OHIO)
Major, M. C., U. S. Army; Chief of Medical Service, Base Hospital
AND
GEORGE W. SWIFT, M.D. (SEATTLE)
Captain, M. C., U. S. Army; Brain Surgeon, Section of Head Surgery, Base Hospital
FORT RILEY, KAN.

At the time of the epidemic of influenza[1] and influenzal pneumonia, the military population of the United States Reservation at Fort Riley was 63,374, distributed as in Table 1.

The total number of cases of influenza were divided as shown in Table 2. The influenza incidence for the population of the military reservation was 23.9 per cent.

As will be observed in Table 3, 2,624 instances of pneumonia occurred during the epidemic, of which 2,496 were definitely traccable to influenza.

Empyema (not carried as pneumonia but *resulting* from epidemic)	65
Deaths from pneumonia	941
Total	2,624

The largest number of influenza and pneumonia patients admitted to the base hospital was on September 30, when 785 were received. The largest total number of patients in the hospital was 5,666, October 8, of whom 2,951 had influenza and 719 influenzal pneumonia. The largest number of pneumonia patients at one time under treatment in the base hospital was 1,338, October 15, as shown in the accompanying chart. The incidence of pneumonia among influenza patients was 17.2 per cent (2,624 in 15,170).

Varying degrees of lung involvement associated with bronchitis occurred among all influenza patients. The evidence in many instances appeared insufficient to warrant a diagnosis of pneumonia, but it must be conceded that the differences were rather of degree than of kind. It is extremely probable that many more influenza patients had patches of lobular pneumonia than were diagnosed as having them, progressing rapidly to recovery in seven or eight days. We have no evidence from this series that death occurred in influenza except from pneumonia or its complications.

The total number of deaths from pneumonia during the epidemic was 941, a pneumonia mortality rate of

---

[1] The term "influenza" is used in the commonly accepted sense cover t epidemic of acute respiratory disease, for the i of wh nzae, or an unknown virus, may be responsi

35.8 per cent. During this period ninety-five deaths from pneumonia occurred in which there appeared to be no evidence of preceding influenza. It is reasonable, however, to assume that influenza was the contributing cause of the acute respiratory infection. The total death rate as a result of influenza was 6.2 per cent.

The death rate from pneumonia did not reach its height until about one month after the epidemic began. The largest number of deaths (eighty-one) occurred October 13.

Among 941 fatal instances of pneumonia, the admission diagnoses are given in Table 4 and the final clinical diagnoses in Table 5. The average length of illness in the hospital before death was 7.3 days, and the average length of hospital residence for the recovered patients, 21.6 days.

TYPES OF INFECTION

Table 7 shows the prevailing types of infection reported by the laboratory for 928 specimens of sputum examined during the epidemic. Since cultures and type determinations were made only for patients with pneumonia or those with suspected pneumonia, the table represents the types of respiratory infection recognized during the epidemic. Because of the labor involved it was impossible to secure routine specimens for all patients.

Among seventy-seven fatal instances of influenzal pneumonia, the organisms isolated prior to death were as given in Table 8.

Among 163 instances of influenzal pneumonia in which the patients recovered, the organisms isolated were as given in Table 9.

NECROPSY FINDINGS

In a series of fifty-five necropsies, lobar pneumonia was present in eighteen instances, or 32.7 per cent.; bronchopneumonia in fifteen instances, or 27.2 per cent.; while lobar pneumonia and bronchopneumonia were found combined in twenty-two instances, or 40 per cent. This large percentage of combined lobar pneumonia and bronchopneumonia (massive pneumonia) was more marked than had been earlier observed in a series of more than 200 pneumonia necropsies during the same year.

In lobar pneumonia, both the left and the right lungs were involved in 23.6 per cent.; the right lung alone in 5.4 per cent., and the left lung alone in 3.6 per cent. The various pathologic lesions are shown in Table 10.

PATHOLOGY

General Pathology.—The most striking involvement of organs usually not particularly associated with the pathology of pneumonia has been emphasized in this series. This refers particularly to the brain, the sinuses, the middle ear and the myocardium. It will be noticed that, despite the prevalence of the streptococcus at necropsy, only eight instances of so-called interstitial pneumonia were found in the series of fifty-five necropsies. We believe, from an experience in a series of 200 cases of pneumonia of interstitial type last March and April, that the pathologic picture depends much on the time of death, the time of death being largely dependent on the systemic invasion of the tissues by the infection. If the pneumonia is essentially streptococcic, and early systemic invasion occurs, death occurs early, with the pathologic picture of interstitial pneumonia. If streptococcic systemic invasion occurs later, for reasons not explainable except on the basis of varying antecedent types of associated infection or specific resistance, death occurs later and the pathologic picture no longer shows interstitial pneumonia but shows massive involvement brought about through the confluence of many areas of peribronchial infiltration involving many lobules and eventually entire lobes. The difference is one of degree rather than of kind. In this series of influenzal pneumonias the interstitial type was uncommon, while massive involvement of both lungs was frequently seen. As will be noticed under necropsy cultures, the streptococcus was the preponderating type of infection. Systemic invasion occurred late, since the average stay in the hospital before death was more than seven days.

It will be noticed that, despite the difficulties in the diagnosis of the type of pneumonia before death, the clinical and necropsy findings were in close accord in that bronchopneumonia was diagnosed clinically in 23.8 per cent. and found at necropsy in 27.2 per cent.; lobar pneumonia was diagnosed clinically in 76.2 per cent. and found at necropsy in 72.6 per cent.; while the combined forms of massive pneumonia were diagnosed as indeterminate clinically in 23.9 per cent., and at necropsy were found to occur in 40 per cent.

Frontal sinusitis	2	4.9	
Ears:			
Otitis media and mastoiditis	17	41.4	

* The term "dilatation" refers to a relaxed and thinned condition of the walls of the ventricles, associated with increased size and increased patency of the valvular orifices. Definite parenchymatous degenerative changes existed in the myocardium in many instances.

Among the associated changes, chronic tuberculosis was present, involving the lungs and glands of the hilum in five instances, or 9 per cent. Acute endocarditis was not observed. Substernal pus pockets, so frequently seen in streptococcus pneumonia following measles, were absent. Pulmonary thrombosis occurred in one instance involving the right branch of the artery and extending with many ramifications into the smaller branches. The patient lived twelve hours. At necropsy the left femoral vein contained a thrombus occupying about 6 inches of its lumen. One sudden death occurred during sleep, five days after convalescence from pneumonia. The necropsy revealed enormous dilatation of the right ventricle; the heart apex was in the left anterior axillary line, the right border four finger-breadths to the right of the sternum. Thrombosis of the anterior tibial artery occurred in two instances subsequent to pneumonia followed by dry gangrene of the affected foot. In one of these patients about a week after a Chopart amputation of the foot, a partial pulmonary thrombosis occurred involving the left pulmonary artery, with an area of consolidation posteriorly (tubular breathing and whispered voice) about 10 cm. square, due to the infarction. Bloody expectoration was delayed for about forty-eight hours. Sudden dyspnea with rapid heart rate and moderate cyanosis occurred coincident with the physical findings. Recovery occurred.

Brain Pathology.—Edema: Edema of the brain, as observed in this series of necropsies, was marked. The arachnoid was widely separated from the pia. The cerebral vessels were distended; the ventricles were dilated; the optic nerve sheaths were so separated as to appear like funnels about the nerves. In some cases a plastic exudate appeared along the vessel margins; cultures of the exudate were taken in only a few instances. These cultures revealed pneumococci.

Meninges and Ventricles: The meningitis was of the subacute basilar type. It was not always present; but when edema was marked, it was invariably associated with a slight plastic exudate. The dura in some instances clung to the arachnoid, especially along the base of the brain. The exudate associated with the edema formed a mat about the greatly distended cerebral vessels. This was especially noticeable where the choroidal plexus had its origin along the under surface of the velum interpositum. This "basilar mat" of vessels and exudate was thickened and gelatinous in those cases in which distention of the ventricles was most marked. The veins of Galen were matted with the plexus. The underlying aqueduct of Silvius showed partial occlusion; its roundish shape was flattened. The distention of the lateral ventricles seemed to be due to this "basilar mat" of vessels and exudate. The outflow, through the veins of Galen, was blocked because of this exudative process. This accounted for part of the distention of the ventricles, while failure to relieve the distention by spinal puncture could be attributed to the occlusion of the aqueduct of Silvius. In no case were hemorrhages found in the basilar nuclei.

Sinuses: After removal of the brain, the dura of the base was examined for inflammation due to extension from the sinuses and middle ear. In no case could any connection be determined. The sphenoid was approached from the sella after removal of the pituitary body. In twenty-eight cases (68.3 per cent.), pus was present; in some it was under great pressure and drained for several minutes, while in others it was scanty. That it was a frequent complication early in the infection was proved; but that it was always present or that it was the primary localizing point of infection was not found true in this series of cases. The prevailing type of infection was a hemolytic streptococcus, which was present singly or in combination in 46.4 per cent.

The ethmoid sinus was involved on one or both sides in only thirteen cases (31.7 per cent.), a relatively small number; but this percentage increased during the epidemic. The frontal sinus was infected in only two cases. A rudimentary frontal sinus on one or the other side was not uncommon. The prevailing type of infection was a hemolytic streptococcus, which was present singly or in combination in 25 per cent.

The Middle Ear and Mastoid.—In seventeen cases (41.4 per cent.), either one or both middle ears were involved. In two cases, an acute congestion was noted. In the others, a thin, yellow pus filled the cavity as well as the mastoid cells. There was no bone necrosis in the mastoid, even in cases of several days' duration. On section, the pus drained freely, leaving glistening surfaces. The drum membrane was apparently normal. The amount of pus that would drain into the cranial fossa was surprisingly large in quantity. The absence of bone infiltration was perhaps the most surprising feature. Extension of the infection to the cells of the mastoid was present in every case examined. The prevailing type of infection was a hemolytic streptococcus, which was present singly or in combination in 35.3 per cent.

Pneumococcus	1	12.5
Streptococcus hemolyticus	2	25.0
Nonhemolytic streptococcus	1	12.5
Micrococci, type undetermined	1	12.5
Gas-forming bacillus*	3	37.5

* An unknown bacillus isolated in all from 9 cases by Major Oscar F. Broman, M. C., chief of the laboratory service, was frequently obtained by cultures of tissues from the mediastinum, neck, chest and mesentery, in which an unusual development of gas formation had occurred during the course of the pneumonia. Major Broman has thus described the organism: Morphology: rod-shaped with rounded ends; length from 1 to 6 microns; central spores were formed in forty-eight hours' growth. Stain: gram-positive; also stains with ordinary anilin dyes. Motility: slight, flagella present. Cultures, facultative anaerobe; gas is produced; grows in ordinary mediums; liquefies gelatin; forms acid in litmus milk and Hiss serum water. Sugars: The simple sugars are markedly fermented, the disaccharids to less degree, the polysaccharids slightly or not at all. Pathogenicity: low for guinea-pigs, rabbits, mice, rats and for man. Does not produce necrosis or gangrene of tissues.

BACTERIOLOGIC FINDINGS

Reference to Tables 8 and 9, showing sputum examinations in seventy-seven fatal instances of influenzal pneumonia and 163 instances in which recovery occurred brings out the interesting fact that hemolytic streptococci were not reported in the sputum of any of these patients, while cultures made at necropsy revealed this organism as the preponderating type of infection in a great many instances.

The result of seventeen blood cultures, made during the week of October 11-18, from patients with influenzal pneumonia or some complication, is given in Table 13.

A series of nasopharyngeal cultures on influenza patients was made by the laboratory staff at Camp Funston during the height of the epidemic, from September 25 to October 19. Human blood-agar plates were used. The results are given in Table 14.

SUMMARY OF EVIDENCE OF INVASIVE FEATURES BY B. INFLUENZAE

B. influenzae was the predominating organism obtained in 35.7 per cent of 300 nasopharyngeal cultures from influenza patients. Among 928 sputum cultures from influenzal pneumonia patients, the majority of whom recovered, influenza bacilli were found in 18.7 per cent. Among seventy-seven instances of fatal influenzal pneumonia, the sputum cultures revealed influenza bacilli in only 5.2 per cent.

This evidence strengthens the belief that the influenza bacillus, or some unknown virus, merely served to predispose to pulmonary infection with organisms commonly known to produce pneumonia, such as the pneumococcus and *Streptococcus hemolyticus.*

TYPES OF INFECTION RESPONSIBLE LOCALLY FOR INFLUENZAL PNEUMONIA

It is well known that in any epidemic of acute respiratory disease the organisms responsible for the development of pneumonia are usually those that have been demonstrated to prevail commonly in the particular locality. For about one year prior to the onset of this epidemic of influenzal pneumonia, the hemolytic streptococcus (with the exception of two months, July and August) had been the preponderating type of infection in the U. S. Military Reservation, Fort Riley. It had been responsible for many fatal pneumonias, for the serious complications in pneumonia (68.4 per cent. of 155 operative empyemas[2]), for many mastoid infections, and for many acute surgical conditions. We were not surprised, consequently, at its prevalence as the associated type of infection in the pneumonias that followed influenza. If one ascribes to the hemolytic streptococcus the rôle of secondary invader it does not in any way lessen its importance. In seventy-seven fatal instances of influenzal pneumonia and 163 cases with recovery, this organism was not found in the sputum cultures. It was found in only 1.7 per cent. of 300 nasopharyngeal cultures from influenza patients, and yet, in fifty-five pneumonia necropsies this organism was obtained in 41.1 per cent. of tissue cultures. It was, in addition, obtained from 41.5 per cent of the pleural fluids of sixty-five patients with empyema who came to operation as a result of the epidemic.

---

[2] Stone, W. J.; Phillips, B. G., and Bliss, W. P.: A Clinical Study of Pneumonia Based on Eight Hundred and Seventy-One Cases, Arch. Int. Med. 22:409 (Oct.) 1918.

It is well known that the tonsil crypts harbor the hemolytic streptococcus in from 75 to 85 per cent. of those examined by various workers. Mouth carriers of this organism are relatively common. This organism has also been frequently isolated from many other tissues not always associated with disease processes. The fact that the nasopharyngeal cultures were so largely negative for this organism in this series does not mean, of course, that the infection did not exist in the tonsils. It seems fair to assume that its presence in the tissues of the body may not be, in the vast majority of instances, incompatible with health; but it is evident, in view of the necropsy findings here recorded, that whatever organism or virus may be responsible for the acute respiratory invasion, the hemolytic streptococcus, whether introduced from within or from without, became the most serious factor in the production of high mortality.

CLINICAL FEATURES

Bleeding from the nose and lungs was relatively common. Cyanosis was marked comparatively early in the course of the disease and was not, in the majority of patients, associated with air hunger. It was not relieved by venesection. The heart rate was not markedly increased in many instances until shortly before death. A rate of from 100 to 104 was not uncommon. Prostration out of all proportion to the apparent extent of pulmonary involvement was marked. In the majority of patients a remission in the fever occurred about the third day and proved a deceptive feature. Many patients manifested a recrudescence of lung symptoms with increased fever on the day following and, with increasing stupor or delirium, died in from sixty to seventy-two hours. Leukopenia was almost a constant feature. Leukocyte counts of 2,000 per cubic millimeter were not uncommon.

Delirium was a prominent symptom in many patients with pneumonia. This was temporarily relieved by lumbar drainage of from 50 to 70 c.c. of spinal fluid. The congestion of the cerebral vessels with edema, distention of the lateral ventricles and subacute basilar meningitis were the pathologic conditions found at necropsy. These conditions were responsible for the delirium, meningismus, choking of optic disks and increased spinal fluid pressure. In markedly delirious patients the ophthalmoscope revealed a characteristic and more or less constant picture. The fundus vessels were engorged and tortuous, the disks congested, the cup and vessel sheaths edematous. From the necropsy findings (distention of nerve sheaths by edema) one would expect this ophthalmoscopic picture. In no case of known sphenoid involvement, without delirium, were changes found in the ocular fundi. In one case of acute ethmoid sinusitis, a papilledema was noted. This was relieved on drainage of the ethmoids by shrinking the nasal mucous membrane.

The relationship of sinusitis involving the sphenoids and ethmoids to basilar meningitis could not be determined. From the clinical standpoint more attention should be paid to the involvement of these tissues in any acute respiratory infection, since drainage by shrinking the nasal mucous membrane, by means of an aqueous spray of 4 per cent. antipyrin, relieved these conditions.

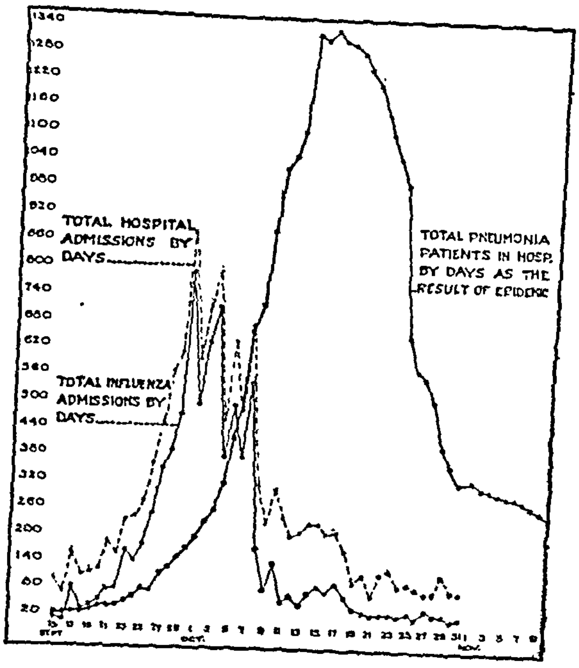
Mastoiditis as a complication of influenzal pneumonia was found in seventeen necropsies (41.4 per cent.). Clinically, otitis media, with tenderness over the mastoid area, was a complication in a great many cases. The first symptoms were dull aching pain and slightly diminished hearing in the affected ear. Examination disclosed a bleb on the tympanum or a bulging drum. Hemorrhage from the external canal, which was not uncommon, signified rupture of the bleb on the tympanum. Such cases were not followed by otitis media, and the pain was relieved. Patients who presented a bulging drum as evidence of otitis media required paracentesis. The findings at necropsy and the roentgenograms of many patients demonstrated that the mastoid cells were involved with the middle ear in all cases. *Streptococcus hemolyticus* was the predominating organism in the cultures from the mastoid as well as the blood stream. Bone necrosis was conspicuous by its absence in the mastoids examined at necropsy. Six patients with otitis media-mastoiditis came to operation. In these six cases the organism found in cultures taken from the cells at the time of operation was *Staphylococcus albus*. This undoubtedly was due to infection from the external auditory canal. The absence of bone necrosis was due to the sudden onset, the prompt drainage of the middle ear, either spontaneously or by paracentesis, and the fact that the patients were in good physical condition at the time of infection. Had the sequence been such as occurs in measles, streptococcus tonsillitis or scarlet fever (an otitis media with gradual involvement of the mastoid cells), extensive bone necrosis would have been the result. The time factor appeared to be of great importance in determining the presence or absence of bone necrosis.

The absence of bone necrosis and the presence of blood stream invasion by *Streptococcus hemolyticus* in this series sheds light on the extensive epidemic of mastoiditis seen at this hospital last winter and spring. The mastoiditis that occurred at that time (164 cases) presented a more serious type of infection. Likewise, *Streptococcus hemolyticus* was the organism isolated in the majority of cases. The otitis media occurred with a delayed time interval subsequent to streptococcus tonsillitis, measles or scarlet fever. This type of otitis media was rapidly followed by mastoiditis of the fulminating variety. Operation within forty-eight hours in many instances revealed extensive necrosis of bone. Frequent complications (compared to civil practice) were meningitis and septic arthritis. Exposure of the lateral sinuses and the dura did not account for the invasion of the meninges or blood stream, because in cases in which these structures were not uncovered, the complications developed quite as frequently.

We have gained the impression that there may be a very definite connection between meningitis and the trauma of the mastoid operation, if done with a chisel. The meningeal involvement followed too rapidly to be due to direct extension from the mastoid, and the necropsies showed no connection. The majority of instances of meningitis occurring in pneumonia with an associated otitis media are the result of blood stream invasion. Those instances that occur following a mastoid operation in pneumonia may be precipitated by the trauma; but blood stream invasion is probably the important factor.



Total hospital admissions, influenza admissions and pneumonia patients at Fort Riley, Sept. 15 to Nov. 1, 1918.

Three deaths occurred from influenzal pneumonia developing during the course of meningococcus meningitis, and three deaths resulted from pneumococcus meningitis in patients with pneumonia (without otitis media).

Alkaline drinks were useful in treatment of herpes labialis. Tincture of digitalis, standardized by the cat method of Hatcher and Eggleston, was used according to the body weight of the patient as a routine measure. Edema of the lungs, with the expectoration of large quantities of blood-tinged foam, was a conspicuous incident in many fatal cases. The presence of severe pleural pain with expiratory grunt was always suggestive of effusion twenty-four hours later.

In about thirty instances, subcutaneous emphysema was noticed. It was not always fatal, but occurred frequently among patients who died. The emphysema was usually first noticed at the suprasternal notch, and spread rapidly over the chest, neck, scalp and abdomen to the thighs. Its development did not seem to be associated with severe paroxysms of coughing. Empyema occurred in less than 10 per cent. of the pneumonias. This was in marked contrast to our experiences earlier in the year, in which empyema occurred in 200 of 871 completed cases of pneumonia (22.9 per cent.).

SUMMARY

1. Among a military population of 63,374, an acute respiratory disease called influenza appeared in epidemic form affecting 15,170 individuals (23.9 per cent.).

2. The incidence of pneumonia among influenza patients was 17.2 per cent.

3. Among 2,624 pneumonia patients, 941 deaths occurred in forty days, a mortality of 35.8 per cent.

4. The final clinical diagnoses among 941 fatal instances were: lobar pneumonia, 76.2 per cent.; bronchopneumonia, 23.8 per cent. At necropsy, in fifty-five instances, the diagnosis of combined lobar pneumonia and bronchopneumonia (massive pneumonia) was made in 72.6 per cent., bronchopneumonia in 27.2 per cent.

5. Among 300 nasopharyngeal cultures from influenza patients on human blood agar, *B. influenzae* was the predominating type of infection in 35.7 per cent. In the sputum cultures from 928 pneumonia patients, *B. influenzae* occurred singly or in combination in 18.7 per cent. Among seventy-seven fatal instances of pneumonia, *B. influenzae* was found in the sputum cultures in 5.2 per cent.

6. At necropsy, in fifty-five instances of pneumonia, cultures from the lungs, pleural fluids, heart's blood, sinuses, mastoids and tissues revealed the pneumococcus in 56.1 per cent., and *Streptococcus hemolyticus* in 41.1 per cent. The hemolytic streptococcus was, in addition, isolated in 41.5 per cent. of sixty-five empyemas resulting from the epidemic. This was to be expected since the hemolytic streptococcus had been the predominating type of associated infection in pneumonia throughout the preceding year in this locality.

7. No deaths occurred in this epidemic except from pneumonia or its complications. Although the hemolytic streptococcus was responsible for death in the majority of instances, interstitial pneumonia was not a prominent feature. When death occurred early in streptococcus pneumonia (three or four days), the pathologic picture was that of the interstitial variety. This was particularly true of the pneumonia following measles, as judged by earlier experience with this type of infection. When death occurred at a later period, as in this epidemic, it appeared that through the confluence of many areas of peribronchial pneumonia, contiguous lobules and eventually entire lobes or a whole lung had become involved in a massive type of pneumonia.

8. Systemic invasion of many organs and tissues by the infections responsible for the pneumonic process (the pneumococcus and streptococcus) was evident at necropsy. This refers particularly to the brain and meninges, the middle ear, mastoid and sinuses.

9. In forty-one necropsies, meningitis of subacute basilar type associated with edema was a striking feature in 58.5 per cent., while brain edema without meningitis was present in 21.9 per cent. Otitis media and mastoiditis existed in 41.5 per cent., while sphenoiditis was present in 68.3 per cent. and ethmoiditis in 31.7 per cent.

10. Bone necrosis of the mastoid was conspicuously absent in influenzal otitis media and mastoiditis. This

was in marked contrast to otitis media following measles, streptococcus tonsillitis or scarlet fever in which, because of the length of the preceding illness and the condition of the patients, the development of middle ear infection was delayed; but when it occurred mastioditis was rapidly followed by bone necrosis.

CONCLUSIONS

1. *B. influenzae* had not been frequently encountered in the sputum or throat cultures of patients in this locality during the year preceding the outbreak of this epidemic.

2. From the facts given it appears that *B. influenzae* or an unknown associated virus was responsible for the invasive features of this epidemic of acute respiratory disease, but that, as the cause of death in the subsequent pneumonias and their complications, the pneumococcus and the hemolytic streptococcus, which was associated with it and which was an organism prevalent in this locality, were largely responsible.

3. From experience based on the study of 1,100 patients with pneumonia treated in the medical service of this hospital during the year preceding this epidemic, it is believed that pneumococcus pneumonia, when the hemolytic streptococcus is not prevalent or associated with it, is a disease with relatively low mortality. During an interval of two months (July and August, 1918) preceding this epidemic, in a series of 151 instances of pneumococcus pneumonia the mortality was 9.9 per cent. During these months the hemolytic streptococcus was rarely encountered (1.8 per cent. of 162 sputum cultures), and but one empyema occurred, the causative organism being the pneumococcus.

4. Generalized systemic invasion by the combined infections producing pneumonia occurred in many instances in this epidemic. On the time of such systemic invasion in a pneumonia patient depends, to a large degree, the time of death and the extent of the pathologic processes seen at necropsy. Blood stream invasion with involvement of many organs due to breakdown of defensive barriers may occur only a short time before death. This explains the large percentage of negative blood cultures in pneumonia, unless taken shortly before death.

5. As a source of information concerning the type of infection present in acute respiratory disease suspected to be due to the hemolytic streptococcus, because of its prevalence in any locality, cultures from tonsil surfaces and crypts on blood-agar plates are recommended.

6. Otitis media occurring during the course of influenzal pneumonia, especially if due to the hemolytic streptococcus, has, in this series, always been accompanied by mastoiditis. Drainage of the middle ear should be promptly secured. Failure to establish drainage may result in bone necrosis of the mastoid, which alone is indicative of imperative operation. Bone necrosis can be detected by roentgenograms so taken as to compare the sound with the affected side on the same plate. At time of operation, as little trauma as possible is essential. The use of the electric bone drill in removing the outer table decreases the trauma.

7. A dull occipital headache in influenza or pneumonia is suggestive of sphenoid sinusitis. Shrinking of the nasal mucous membrane by means of a spray of a 4 per cent. aqueous antipyrin solution affords relief.

8. Lumbar drainage in delirious pneumonia patients is not only a source of diagnostic information but also is a therapeutic measure of value. This should be repeated as frequently as appears necessary to relieve the pressure of fluid.

9. Tincture of digitalis, standardized to definite dosage and administered to full estimated requirement during the first twenty-four to thirty hours in pneumonia, has lessened the deaths that might be attributed to circulatory failure.

10. The most common complications in this epidemic of influenzal pneumonia were pleural effusions, empyema, pericarditis (serofibrinous or purulent), cerebral edema and meningitis, otitis media and mastoiditis, sphenoid and ethmoid sinusitis and nephritis.

11. Specific pneumococcus antiserums supplementing Cole's Type I serum are much to be desired, but more attention should be directed to the rôle played by the hemolytic streptococcus in the production of the epidemic types of pneumonia.

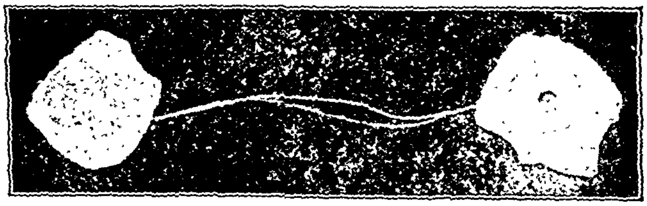
12. It is believed that not much may be expected in the specific treatment of pneumonia of the type associated with the presence of the hemolytic streptococcus until a potent antiserum for the various strains of this organism has been produced. Many serums designated as polyvalent are on the market, but opinion is by no means unanimous as to their value in the treatment of pneumonia.

Clinical Notes, Suggestions, and New Instruments

A GOOD TENSION SUTURE

Rembert H. Thigpen, M.D., Jerome, Ariz.

In this suture are employed one or more strands of silkworm gut; two small gauze sponges; two metal buttons, each the size of a 25-cent piece, and perforated at its center with a one-sixteenth inch hole, and two or more perforated shot. The sponge, button and shot holding each end of the intestine are placed a suitable distance from the line of incision, and tightened to secure the desired approximation. There occurs a pronounced ridge along the line of incision. The ends of the absorbable subcuticular suture closing the skin are treated as are the tension sutures.



Complete tension suture.

Cost of Preventable Sickness.—A recent survey of five townships in Duchess County, made by the State Charities Aid Association, disclosed the fact that preventable sickness was costing the county at a conservative estimate $412,000 a year in actual money, to say nothing of continued invalidism, bereavement and loss of productive power to the community which could not be estimated. A close study was made of 1,600 cases of serious illness and it was estimated that the county was losing 9,000 working days by men and women, and 13,700 school days, and that these two items alone were costing the community $25,000 a year.—Report of Duchess County (N. Y.) Health Association.

SCIENCE AND WAR BREAD

It has required the exigencies of a world war to accord science a more respectful hearing in the councils of everyday life and industry. In the past the scientist has been tolerated as a sort of visionary, incapable of securing so-called practical results, if he has not actually been snubbed by the cut-and-dry type of American. The past four years have shown conclusively, however, that the heralded genius for invention cannot be depended on to lead the way out of patent difficulties in times of great stress. Hence the refuge in the man of science as a last resort.

The food conservation movement brought our nation face to face with the necessity of using substitutes for wheat, the mainstay in our "daily bread." There can be no question as to the comparative wholesomeness of other cereals like corn, rice and barley—a conclusion for which we are indebted in turn to scientific investigation as well as to experience. But wheat has been the cereal *par excellence* in the preparation of that special dietary article, bread, which the entire world seems to crave. What special qualities render wheat so superior in baking the loaf? What are the unique characteristics that have put it into the foreground so prominently as to give it an established place in the world's common rations? Of course it has long been taught that the advantage is essentially due to the mixture of unusual wheat proteins which are insoluble in water and are commonly designated as gluten. The swollen, coherent gluten imparts to wheat-flour dough those properties of tenacity and elasticity that are peculiar to it. It permits the stretching and distending of the mass in bread making so that as the result of the action of yeast in fermenting the carbohydrates present the volume may increase four or five fold.

Innumerable difficulties in bread making are so frequently referred to that many have almost despaired of securing any trustworthy solution. The industry has at length become organized to a point at which science has been called on to lend a helping hand[1] in order to enable the practical art to keep pace with the progress of biochemistry. The extent to which the dough can be distended varies with the quantity and the physical quality of the gluten, as has long been demonstrated. But we are now shown how the baker can, within certain limits, improve the rising of the dough by modifying the physical condition of the gluten. The latter is profoundly influenced in its properties, as many proteins are now recognized to be, through the presence of acids or certain salts. According to Cohn and Henderson,[1] who have investigated these factors for the Division of Food and Nutrition in the medical department of the U. S. Army, the acidity of the dough at the time of baking *seems to* be the most important variable factor in bread making. Accordingly, simple procedures have been devised for measuring and correcting this factor.[2] The hydrogen-ion concentration of bread is related to the original acidity and to the acid-combining power of the cereals used, to the amount of yeast, and in that the activity of yeast varies with the acidity of the medium and modifies it through the acid products of its own metabolism, to the conditions of fermentation. The importance of accurate information about acidity is herewith made clear. Nothing could be simpler than the method proposed: a few drops of a solution of methyl red allowed to fall on a slice of bread, and a color chart for comparison, comprise the outfit.

These features scientifically attained, let it be reiterated, have already enabled bakers to overcome not only difficulties in the technology of bread making but also certain annoying pathologic manifestations. Ropy bread is produced by the action of certain micro-organisms, notably members of the *Bacillus mesentericus* group, of which the spores survive the heat of the oven and later attack the center of the loaf. This has been a factor of serious economic importance, greatly exaggerated by war-time conditions. It has now been demonstrated by Cohn, Wolbach and Henderson[3] at Harvard University that the organism responsible for rope cannot develop in bread when the acidity is of suitable character—an item that can now be gaged with mathematical accuracy. Measured additions of lactic acid to the dough constitute a prophylactic agency. This is a matter of no little moment at a time when there are large variations in the acidity of bread resulting from the changing formulas and different substances that bakers of late have been forced to use.

But there remains the deficit of gluten, despite all physicochemical adjustments of its properties, when other cereals must take the place of wheat. Skilful fermentation and control of acidity cannot make up for lack of gluten in wheat substitutes. However, the

---

[1] For a discussion of the subject, from which many of these statements are borrowed, see Cohn, E. J., and Henderson, L. J.: The Physical Chemistry of Bread Making, Science, Nov. 22, 1918, p. 501.

Harvard investigators have demonstrated that a small addition of serum protein to doughs containing wheat substitutes functions much like the gluten and materially lessens the difficulties that have existed in the production of "victory" products. Bread prepared with blood is not an entire novelty. It may be psychologically unattractive or even objectionable to those who are vegetarians by faith; but to quote the scientific verdict, "if it is inferior to bread made of pure wheat flour, it possesses certain important qualities of its own, and its use seems to be in all respects quite unexceptionable."

THE SCIENTIFIC ASSEMBLY OF THE AMERICAN MEDICAL ASSOCIATION

The criticism has been made that the annual sessions of the Scientific Assembly of the American Medical Association are entirely too strenuous; too many section meetings go on at the same time, and practically every minute is occupied by scientific work, even the evenings often being given over to scientific work rather than social functions. The number of papers on the programs of all the sections have run as high as 350 or 400. There is no other scientific or medical convention, state, national or international, at which so many papers are read or so much scientific material is considered. In this country there is only one other convention that is similar in character—the Congress of Physicians and Surgeons of North America—which has met every three years at Washington. This is composed of some ten or twelve special societies which might be compared with the sections of our Scientific Assembly. These special societies meet only in the morning, as there is a general meeting in the afternoon which the members of the special societies are supposed to attend. Actually the afternoon and evening sessions are more social than scientific. The British Medical Association is more comparable with our association. Those who have attended the annual sessions of the British Medical Association have quickly noticed a difference—its scientific work is confined to the morning hours, while the afternoons and evenings are given over to social matters, garden parties, conversazioni, tea, cricket and what not. Our British confrères seem to devote a large portion of the time at their annual meetings to having a good time and to forming new and renewing old acquaintances.

While the British Medical Association's scientific program provides for many sections, most of them hold but one or two meetings during an annual session and usually have a very short program, frequently only two or three papers. With an increasing number of sections, our annual sessions have become more and more strenuous; for those who are attached to any particular section, attendance on these meetings becomes a drudgery—hard work without relaxation. There should be a happy medium. Primarily the sections of the Scientific Assembly are for the dissemination of scientific knowledge among the Fellows; almost, if not quite, as important an object of these annual meetings should be the social aspect, the getting acquainted with other physicians, not only with those interested in a similar kind of work, but also with physicians and medical interests in other fields.

Our Scientific Assembly is a combination of fifteen, sometimes sixteen, sections. In the past, these sections have all met at the same time, both morning and afternoon, during the three days devoted to section work; and this, notwithstanding the fact that a large majority of the Fellows who attend these annual sessions are not especially interested in the work of any one section. Most of them are attracted by the programs of several or all of the sections. Many Fellows are confused by the multiplicity of good things placed at their disposal. Frequently they become bewildered by this complexity of the program and fail to take advantage of any of the scientific work.

These faulty conditions have been recognized for some time. They constituted the first problem taken up by the Council on Scientific Assembly. In 1917, the Council proposed a plan for abating the evil. This provided for three meetings for a majority of the sections, but allowed certain others to hold five or six. The plan was adopted, but later in the session a protest was made, presumably because the scheme favored certain sections to the disparagement of others, and the House of Delegates reconsidered its action. Last year, the House directed the Council on Scientific Assembly to study this problem and to formulate a definite plan of procedure for future meetings. In compliance with these instructions a tentative program was worked out by the Council and was presented to a meeting of the secretaries of the sections held in Chicago, February 6. This scheme was the same as that adopted in 1917, except that all sections were treated alike. The secretaries discussed the subject thoroughly and were enthusiastic in favoring its adoption. It was agreed, further, that the proposal should be put into effect this year at Atlantic City.

Each section at the coming Scientific Assembly will be limited to one meeting each day, half to hold morning sessions and the other half afternoon sessions. Special attention was given to the grouping, so that sections devoted to allied subjects will alternate. For example, the ophthalmologist may attend his own section in the morning and that on laryngology in the afternoon; the internist may attend the Section on Practice of Medicine one half day, and the other half day the Section on Surgery, Pathology or Pharmacology. Loyalty to a particular section has been and is an important factor in developing the Scientific Assembly of the Association. However, the new arrangement will encourage rather than discourage full attendance on the sections in which a Fellow may be particularly interested. He will now be able to attend other sections without his conscience being disturbed by feeling that he is neglecting that section to which he should give his entire allegiance.

The new arrangement simplifies the programs, equalizes attendance on the sections, broadens the scope of the discussions, and, finally, affords opportunity for social gatherings.

A NEW RECORD FOR ALTITUDE

One of the scientific by-products of the war has been a greatly enhanced understanding of the physiology of altitude. Only a few years have elapsed since the establishment of an international physiologic laboratory on Monte Rosa in the Alps, an undertaking sponsored by the late physiologist Angelo Mosso of Turin to promote the investigation of the numerous obscure questions relating to human welfare and functioning at considerable heights. By studies made there and elsewhere, mountain sickness has been shown at length to be due fundamentally not to the merely mechanical effects of decreased air pressure in the ears and on the blood vessels, but rather to oxygen deficiency attributable to the low partial pressure of this gas at considerable altitudes.

The institution of aviation as a practical performance has raised novel problems in relation to travel at high altitudes. To the fundamental question of the effect of the barometric pressure per se has been added the complicating circumstance that the aviator does not ascend or descend slowly and secure any benefits of gradual adjustment to new conditions or any real acclimatization. On the contrary, he is subjected to sudden physiologic strains of considerable severity. These features were reviewed in a series of papers in The Journal under the title "Medical Studies in Aviation."[1] The investigations of the Medical Research Laboratory of the Air Service at Mineola, L. I., have demonstrated the possibility of studying many of the factors of aviation as it concerns the aviator by exposing the individual to partial pressures of oxygen comparable with those likely to be encountered in air travel. Thus a person confined in a closed chamber from which the air is partially exhausted will experience phenomena of malaise with which observers of symptoms at high altitudes have made us familiar. Mere withdrawal of the oxygen alone, such as occurs by rebreathing air in a confined space, whereby this gas is gradually used up, likewise suffices to induce the symptoms. In either case they can be relieved by administration of oxygen; and the altitude effects can be averted if oxygen is respired in due season as a precautionary measure.

In studies of this sort by the physiologic experts of our air service, the possibility of enduring barometric pressures comparable to an altitude of 35,000 feet has been convincingly demonstrated, the proper supply of oxygen having been maintained during the diminishing air pressure. It is of no small interest, nevertheless, to learn that the demonstrations thus provided in tests on the ground have been verified under the actual conditions of flight in the air itself. Within the past few weeks Captain Lang, the Australian aviator, accompanied by Lieutenant Blowes, in a flight from England has recorded the achievement of the world's record for altitude by reaching the height of 30,500 feet, or nearly six miles, in a biplane. To accomplish this it was necessary to ascend into air thinner than that which is pierced by Mount Everest.

How important the oxygen factor is in such performances is certified by the collapse and unconsciousness of Blowes at an altitude of 20,000 feet, owing to a defect in the tube supplying him with oxygen. At the maximum altitude reached, a temperature of 38 F. below zero was recorded, that is, 70 degrees below the freezing point of water. The aviators suffered severely from the cold despite the devices adopted to keep them warm. It is not improbable that this feature of life at very high altitudes will offer a greater practical difficulty than the more readily remediable diminution in the partial pressure of oxygen. In the case of mountain climbers the problems of relieving oxygen shortage and suffering from cold are augmented by the extreme muscular exertion required under most unfavorable conditions for exercise. Whether the "highest spires" of the world can ever be climbed cannot be decisively answered from physiologic considerations alone; but with Mount Everest attaining a maximum of only 29,000 feet, we may safely admit the contention of a recent commentator, who stated that "the new lord of height is the airman."

CALCIUM AND INFANTILE TETANY

As The Journal recently pointed out,[1] Noël Paton and his collaborators of Glasgow University have come to the conclusion that the tetany of animals deprived of their parathyroid glands and the idiopathic tetany of man are identical as regards their characters and metabolism. The implication is that an error in the chemical exchanges of the organism results in an intoxication by guanidin derivatives, a disturbance in parathyroid function being assumed to underlie the abnormal conditions. So far, however, as infantile tetany is concerned, Howland and Marriott[2] of the Department of Pediatrics at the Johns Hopkins University insist that enough studies have been made to show that parathyroid lesions in infancy are the exception and not the rule. Furthermore, they maintain that parathyroid lesions as severe as have been found after tetany may occur in patients who, during life, have shown absolutely no evidences of this symptom.

---

[1] The Parathyroids and Idiopathic Tetany, editorial, J. A. M. A. **71**: 1661 (Nov. 16) 1918.

[2] Howland, John, and Marriott, W. McK.: Observations on the Calcium Content of the Blood in Infantile Tetany and on the Effect of Treatment with Calcium, Bull. Johns Hopkins Hosp. **29**: 235, 1918.

In searching for other possibilities of etiologic significance, so far as the tetany of children is concerned, the Baltimore pediatricians have turned their attention to the blood. By a striking series of analytic determinations they have furnished seemingly incontrovertible evidence of a diminution of the calcium in the serum in cases of active tetany. The quantity of this element in the serum of normal infants as well as in placental serum is singularly constant—above 10 mg. and rarely more than 11 mg. per hundred c.c. of serum.

In eighteen cases of idiopathic tetany, on the other hand, it averaged 5.6 mg., being greatly reduced in all cases. Furthermore, it was found that this constancy in the diminution of calcium in the serum—a reduction of 40 per cent. in many instances—affords some means of differentiating tetany from other convulsive disorders in infancy. In rickets, often but not always associated with infantile tetany, there may be a slight reduction in the calcium, but this does not seem to be obligative.

Calcium and magnesium are known to be physiologically antagonistic to each other in some instances. Analyses of the magnesium content of infantile blood justify Howland and Marriott in saying that this element plays no determining rôle in the production of the symptoms of tetany. The logical sequence of the discovery of a lowered calcium content in the blood was to attempt to increase the amount of this alkali earth element. Administration of calcium chlorid with the food has proved efficacious, thus substantiating the hopes of the investigators. They assert that severe or dangerous symptoms must sometimes be held in check by sedatives until calcium in full doses produces its effect. Thereafter only calcium need be given.

These practical contributions to the diagnosis and therapy are of themselves commendable and helpful. Scientific curiosity cannot stop here, however. It seeks the ultimate causes of disease. Howland and Marriott's conception of tetany is that some factor, at present unknown, causes a reduction of the calcium content of the blood. When this drops to an amount roughly between 6 and 7 mg. of calcium per hundred c.c. of serum, frank evidences of tetany arise. This amount, however, is not the same with all individuals. With some it may be as low as 5.5 or 6, with others as high as 7.5. These symptoms occur in outbursts so long as the calcium remains low. When the calcium rises, the symptoms disappear. The height to which the calcium must rise in order that the symptoms must disappear is also somewhat variable.

It remains to be seen whether the belief that many of the symptoms of infantile tetany are directly referable to the diminished calcium content of the blood, and that they may be prevented or caused to disappear by calcium therapy, is irreconcilable with other current hypotheses. The "alkalosis" factor noted by some experimenters and emphasized in recent studies of gastric tetany[3] cannot be put aside, though Howland and Marriott found no evidence for it in the serum of infants with tetany. They admit that the symptoms of tetany and the lowering of the calcium content of the blood serum may be produced in a variety of ways. What is the still unknown factor that apparently may effect the same symptom through seemingly unrelated channels? Parathyroid deficiency, alkalosis, lowered calcium in the circulation—these are possible incidents in some profound phenomenon that remains to be discovered.

Current Comment

OHIO FINDS A BETTER WAY

It has long been customary for physicians to oppose bills licensing followers of cults and sects. This attitude was taken originally in the hope of upholding the standards of medical practice, for the public good. In spite of opposition, however, sooner or later the various sects have secured the legislation thus desired. As a result of this attitude of physicians, the public has concluded that the opposition to the passage of sectarian laws is to prevent competition, in spite of the facts that the laws have never restrained the sectarian and that his competition has never been injurious to the physician. Much more serious has been the public belief that such bills were of interest only to physicians, and that so far as they affected the public health the medical profession would protect the interests of the people. The public has never felt any responsibility in the matter, while the medical profession has incurred unjustifiable criticism in its efforts to protect the public. Evidently physicians are beginning to see things in a clearer light. In the Ohio state legislature a bill has been introduced exempting Christian science practitioners from the educational requirements of the state law. When the bill came before the Public Health Committee of the legislature, the usual argument between the Christian scientists and the doctors was expected. Greatly to the surprise of the legislators, however, the chairman of the committee of the Ohio State Medical Association announced that the association would take no position in regard to this bill. He pointed out that the proposed measure would not in any way affect physicians but that it was a menace to the public health, in permitting unqualified and untrained persons to treat the sick. As this is a matter which concerns the health of the people of the state rather than the welfare of physicians, it is only right that it should be settled by the people themselves. The result of this unexpected statement was that the laymen on the legislative committee who had sat by indifferently, expecting that the rights of the public, so far as they were endangered by the measure, would as usual be protected by the physicians, suddenly began to sit up and take notice when they found the responsibility for protecting the health of their constituency placed squarely on their own shoulders. The bill is still before the legislature. The medical profession has performed its full duty in pointing out the danger to public health which would be involved in its passage. Whatever action is taken by the legislature will be with full knowledge of the consequences. This is the ideal attitude for physicians to take, as should have been recognized long ago. The responsibility of protecting the public from disease and of securing better health conditions belongs to the people. It is not the function of the medical profession to maintain lobbies or to endeavor to secure public health measures by political methods. The true function of the medical profession is to advise the people, to show them how to protect themselves. The doctor's mission is to be a teacher and not a political manipulator. The responsibility for public health conditions must rest with the people and not with any special class or profession. The sooner these general principles are recognized, the better it will be for the medical profession and for public health advancement.

---

THE DANGER IN ASIA

Asia is the home of plague and many other pests. At first thought this does not concern us. But the presence of plague in epidemic form, especially in the ports of the Orient, does constitute a menace to Americans. The facilities for travel have brought Asia and our Pacific coast together, while the possession of the Philippines has multiplied the occasions for intercourse with the inhabitants of the Far East. Thus the diseases of Asia threaten to some degree the lives and health of the American population, and the situation regarded from this point of view has been aggravated by the conditions of war. Therefore it may be truly affirmed that the persistence of plague in India and China is a source of danger to this country and one that must be guarded against. All these points have been emphasized previously, but owing to existing circumstances taken in connection with the unvarying persistence of plague in Asia, it seems timely to lay further stress on them. An exchange[1] points out that the present epidemic of plague in Asia began in Hong Kong in 1894 and in Bombay in 1896, and has persisted since then. It was as deadly and widespread as ever during the first three months of 1918, that is, twenty-two years after the original outbreak. Moreover, so long as the rat is infected in a locality, just so long will man be liable to the disease. The obstacles in the way of successfully grappling with the plague problem in Asia are numerous and almost insurmountable. The natives object to wholesale inoculation and rat destruction; hence the only effective mode of procedure is most difficult to carry out. Religious scruples against the slaughter of animals, even vermin, are prevalent throughout India. Consequently it may be taken for granted that plague will continue to persist in Asia; and as it is extremely rife in the two great ports of that continent, Hong Kong and Bombay, it is not an impossibility that it will be conveyed thence to American ports on the Pacific coast, if necessary precautions are not taken. While there is no doubt that our health authorities are awake to the danger, at the same time it is well to know that the danger exists and will exist as long as plague persists in Asia.

SCIENTIFIC PAN-AMERICANISM

In commenting on the Spanish Edition of The Journal,[1] we stated that nowhere could the friendship and close relationship between the republics of the Western Hemisphere be more fruitful than in the field of science, and especially of medical science. An evidence of the fact that our sentiments are reciprocated and that we were voicing ideas that were generally held throughout Pan-America is contained in the letters received from our colleagues in all the Latin American countries in reference to our Spanish-American Edition. The same ideas have inspired editorials appearing in recent issues of the Cronica Médico-Quirúrgica of Havana.[2] These strongly emphasize the point brought out in The Journal and so well expressed in one of these editorials. To quote: "The ties uniting the peoples of America are growing constantly stronger. It is the logical effect of the international political situation which aids in making more effectual this union between the young peoples who are gazing absorbed at the tremendous drama which is being played before our eyes on the other side of the Atlantic. We, like many of our colleagues, insist that it is necessary for us to know each other better, to increase the relations of friendship and confraternity between the sister republics." The Journal may add that it will be only too glad to participate in any movement which has for its object the bringing together, both scientifically and socially, of the physicians of the Western Hemisphere, and to do everything in its power to transfer the project from the realm of expectation to that of accomplishment.

OASES

The country is really going dry. Still there seems to be hope for the alcoholically thirsty. So long as one of the largest mail-order houses in the country continues to sell *Vinum Carnis et Ferri, N. F.* in gallon jugs the drought may not be as noticeable as it might otherwise. Seriously, however, isn't it about time for the professions of medicine and pharmacy to heave into the discard such utterly unscientific combinations as "Beef, Wine and Iron"?

Medical Mobilization and the War

Personnel of the Medical Corps

For the week ending February 7, the Medical Corps contained 22,821 officers, a decrease from the previous week of 603. The Medical Reserve Corps contained 626 officers. The total number of medical officers discharged since the beginning of the war is 13,753.

Archangel Medical Corps for American Troops

The commanding general at Archangel, after a personal inspection of the hospitals and dressing stations of the Siberian forces, has sent a cablegram to the British War Office in which he states that the medical arrangements are excellent. Less than 4 per cent. of the American troops are in hospitals. Evacuation of casualties over 120 miles of road by sledge has been carried out efficiently and with the least possible suffering to the patients. The sanitation of the country is poor, but is being bettered by every means available. There is hospital accommodation for 20 per cent. of the Allied and American troops of the force, and this percentage can easily be increased. It is stated that there are plenty of medical supplies and equipment, including a railway ambulance train accommodating 100 patients; there are also 100 ambulance sledges.

Destination of Sick and Wounded Air Men

The War Department announces that sick and wounded men of the air service flying personnel, on arrival at ports of debarkation will be sent to the U. S. Army General Hospital No. 2, Fort McHenry, Baltimore, or if convalescent to the Air Service Depot, Garden City, L. I., N. Y. Flying personnel patients when convalescent will be sent either to the Military Convalescent Hospital, Cooperstown, N. Y., or to the Air Service Depot, Garden City, L. I. The necessary transport history will be sent with patients in all cases to the medical board at the Air Service Depot.

Slightly Wounded

The following medical officers have been reported as having been slightly wounded: Arthur L. Weisgerber, Capt., Perry, Kan.; John L. Riley, Lieut., Henryetta, Okla.; Francis Michael Ginley, Lieut., Dunmore, Pa.; David Chapman Bull, Lieut., Naugatuck, Conn.; Othel J. Gee, Lieut., Timpson, Texas; Frank H. Long, Lieut., Buffalo; Thel Hooks, Lieut., Smithfield, N. C.; Maurice Exiner, Lieut., New York City; Angus J. Smith, Lieut., Greenville, Fla.; Harold V. Raycroft, Lieut., Brooklyn; Hilmer Thorer Skovholt, Lieut., Williston, N. D.; George H. Spivey, Lieut., Hollandale, Miss.; Walter Williamson Manton, Capt., Detroit; Thomas C. Ross, Capt., Philadelphia, and William Henry J. O'Brien, Lieut., New York City.

Wounded, Degree Undetermined

The following medical officers have been wounded (degree undetermined): Edward H. Atkin, Lieut., Hoisington, Kan.; Harry S. Van Etten, Lieut., Stroudsburg, Pa.; Thomas M. Moore, Lieut., Hagood, S. C.; Eugene Robert Van Meter, Lieut., St. Louis; Samuel J. Marks, Lieut., Philipsburg, Pa.; Paul Rainey McLaughlin, Major, Guysville, Ohio; Martin A. O'Brien, Lieut., Cleveland; Frank Brady, Lieut., Dawson, N. M.; Harvey C. Updegrove, Lieut., Easton, Pa.; William W. Walcott, Lieut., Natick, Mass.; Clinton B. Staley, Lieut., Enfield, Ill.; George L. Stickney, Capt., Baltimore; Myron Hall Farmer, Capt., Newman, Ga.; Arthur W. Hubbard, Lieut., Wyoming, N. Y.; Bertram H. Buxton, Lieut., Providence, R. I.; Guy Seward, Capt., Leola, Iowa; George W. Krick, Lieut., Reading, Pa.; Lee C. Gatewood, Capt., Chicago, and Thomas J. McHugh, Lieut., Nashville, Tenn.

Severely Wounded

The following medical officers have been reported as having been wounded severely: William Mathias Hoel, Lieut., Lockwood, Mo.; John H. Gilpin, Capt., Fort Wayne, Ind.; Gilbert M. Roberts, Capt., Chattanooga, Tenn.; Samuel Zuckerman, Lieut., New York City; Carl L. Cline, Capt., Dayton, Ohio; James H. S. Morrison, Capt., Cumberland Gap, Tenn.; Edwin L. Lawson, Lieut., Sylvester, Ga.; Zodoc L. Weatherford, Lieut., Red Bay, Ala.; Henry B. Beeson, Capt., Cornell, Wis.; George R. Baker, Capt., Tomahawk, Wis.; Leo D. Applewhite, Capt., East St. Louis, Ill.; Myron Hanna, Lieut., Deshler, Ohio; Max R. Charlton, Capt., Spokane, Wash.; Clyde W. Jump, Capt., Tacoma, Wash., and Thomas R. Gagion, Capt., Pittston, Pa.

Prisoners Released

The following officers reported as prisoners have been released from the German prison camp at Villingen: Bernard J. Gallagher, Lieut., Minneapolis; Franklin B. Pedrick, Lieut., Washington, D. C.; James Earl Quigley, Lieut., Adrian, Pa.; John T. Hardesty, Capt., Winfield, Mo.; Arthur A. Mitten, Capt., Milwaukee; Arthur H. Sewing, Capt., St. Louis; Maurice S. Redmond, Lieut., Pittsburgh; Robert B. Rhett, Lieut., Charleston, S. C.; Henry Leo Rothman, Lieut., Washington, Mo.; Guy D. Tibbetts, Lieut., Bennington, N. H.; Dirk Bruins, Major, St. Petersburg, Fla.; Benjamin P. Burpee, Capt., Manchester, N. H., and Howard Francis Kane, Capt., Bangor, Me.

Erroneous Reports

John H. Shaw, Lieut., M. C., U. S. Army, Plymouth, Mass., has been erroneously reported to have been killed in action. ——Walter N. Mundell, Capt., M. C., U. S. Army, Hutchinson, Kan., is erroneously reported to have died from disease.

Missing

The following medical officers have been reported as missing in action: John G. Skilling, Lieut. Lonaconing, Md.; John Walter McElroy, Rebecca, Ga., and Harry C. Preston, Lieut., New York City.

Distinguished Service Awards

The commander in chief in the name of the President has awarded the distinguished service cross to the following named officers:

KARL J. SWENSON, Captain, M. C., U. S. Army, Portland, Ore., 316th Sanitary Train. For repeated acts of extraordinary heroism in action near Very, France, September 28, to October 30, to November 3, 1918. During the drive in the Forest of Argonne, Captain Swenson established and maintained a dressing station at Very under almost constant aerial raids and severe shell fire During the operations between the Lys and Scheidt Rivers this officer repeatedly showed utter disregard for his own life, maintaining liaison between his own advanced dressing station and the battalion aid stations and searching for wounded on the battle field while he was exposed to heavy fire from artillery, machine gun, and snipers.

DONALD MINER, Major M. C., U. S. Army, Jersey City, N. J., 113th Infantry. For extraordinary heroism in action at Ormont Farm, France, October 10, 1918. Major Miner, voluntarily proceeded under heavy shell fire to an advanced aid station. For four hours he worked unceasingly aiding the wounded and evacuating them. Finding that he could work more effectively without his gas mask, he discarded it, so that it would not hinder him in attending wounded men.

LOUIS DIENER, Captain, M. C., U. S. Army, Baltimore, Sanitary Detachment 112th Machine Gun Battalion. For extraordinary heroism in action in the Ravine de la Veux Mechieux, France, Oct. 26-27, 1918. Upon being notified that an enemy shell had struck a dugout occupied by the brigade radio detachment, Captain Diener ran to the aid of the buried men and worked tirelessly to rescue them. Despite the fact that numerous gas and high-explosive shells were falling in the vicinity, he continued his efforts until he was certain that the three men remaining in the ruined dugout were dead.

JOHN F. DOUDNA, Lieut., M. C., U. S. Army, 362d Infantry, Lake City, Mich. For extraordinary heroism in action. This officer was under constant shell fire with his battalion for 17 days, and though he had been painfully wounded by a machine-gun bullet, he remained at his post, rendering first aid to the wounded night and day, performing the duties of two other medical officers who had been incapacitated, in addition to his own. Lieut. Doudna's utter disregard for personal danger and complete devotion to duty made possible the rapid evacuation of the wounded, thus materially keeping up the morale of the combat troops, and alleviating the suffering of the wounded.

WILLIAM R. ARRANTS, Lieut., M. C., U. S. Army, 317th Infantry, Decatur, Tenn. For repeated acts of extraordinary heroism in action in the Bois de la Cote Lemont, France, Sept. 28, 1918, and near Nantillois, France, Oct. 5, 1918. He with his battalion aid unit accompanied his battalion into action in the Bois de la Cotte Lemont and promptly opened his aid station within 100 yards of the front line, where he worked all night under continuous fire giving aid to the wounded. When there was a shortage of stretcher bearers he assisted in bringing in the wounded. Under intense fire he undertook to locate the ambulance dressing station and personally directed the evacuation of wounded to it. In the attack from the Bois de Fay, October 5, he again went with the attacking troops and opened a first aid station in an old cellar with no cover. Under an intense barrage of shrapnel and high explosive shells he performed the most devoted service in attending the wounded working continuously for nine hours until after his unit had been ordered to retire.

REUBEN G. HAMILTON, major, M. C., U. S. Army, Ambulance Section, 101st Sanitary Train, Rockton, S. C. For extraordinary heroism in action near Marcheville, France, Sept. 25-26, 1918. He established and maintained an ambulance dressing station in an advanced and hazardous position, where he labored unceasingly, treating and evacuating the wounded, throughout the day, in full view of the enemy and under heavy bombardment. Knowing that our troops were withdrawing and the enemy was about to enter the town, he continued his aid to the wounded, even after permission to withdraw had been given him by his commanding officer.

OGDEN DOREMUS KING, Lieut., M. C., U. S. Navy, attached to the 6th Machine Gun Battalion, United States Marine Corps. For extraordinary heroism in action near the Bois de Belleau, June 9-10, 1918. On two successive days the regimental aid station in which he was working was struck by heavy shells and in each case demolished. Ten men were killed and a number of wounded were badly hurt by falling timbers and stone. Under these harrassing conditions this officer continued without cessation his treatment of the wounded assisting in their evacuation and setting an inspiring example of devotion and courage to the officers and men serving under him.

WILLIAM TIGNOR GILL, Jr., Lieut., M. C., U. S. Navy, Washington, D. C., attached to the 6th Regiment, United States Marine Corps. For extraordinary heroism in action neaer Vierzy, France, July 19, 1918. He established a forward dressing station behind the advanced lines and for 15 hours treated the wounded and directed their evacuation while subjected to intense front and flank fire and in the absence of adequate shelter. His fearlessness under these conditions saved the lives of many wounded who would otherwise have been lost to the service. He disregarded personal danger and remained in an exposed position in order to give immediate care to the unfortunate.

JOEL THOMPSON BOONE, Lieut., M. C., U. S. Navy, attached to the 6th Regiment, United States Marine Corps, for extraordinary heroism in the Bois de Belleau, France, June 9-10 and 25, 1918. On two successive days in the regimental aid station in which he was working was struck by heavy shells and in each case demolished. Ten men were killed and a number of wounded were badly hurt by falling timbers and stone. Under these harrassing conditions this officer continued without cessation his treatment of the wounded, superintending their evacuation, and setting an inspiring example of heroism to the officers and men serving under him. On June 25, 1918, Surg. Boone followed the attack by one battalion against enemy machine gun positions in the Bois de Belleau, establishing advanced dressing stations under continuous shell fire.

JAMES G. HALL, Lieut., M. C., U. S. Army, 316th Infantry, Atlanta, Ga. For extraordinary heroism in action near Montauville, France, Sept. 12-15, 1918. In spite of severe wounds, including two broken ribs, received on the first day of the action, he continued at his post for three days, administering aid to the wounded throughout the combat. Numbers of lives were saved by his heroism and devotion to duty.

ROBERT O. BLOOD, Capt., M. C., U. S. Army, 103d Infantry, Concord, N. H. For extraordinary heroism in action near Bouresches, France, July 20-23, 1918. He remained with his battalion during the entire advance working untiringly under heavy enemy fire at all times, superintending the evacuation of the wounded and caring for them in the most dangerous and exposed positions. On July 22 he established his dressing station in an advanced position that was constantly under shell fire, and many times left his station to go into the front lines to treat the wounded.

ROBERT H. MURDOCK, Lieut., M. C., U. S. Army, 47th Infantry, Wilkes-Barre, deceased. For repeated acts of extraordinary heroism in action at Sergy, France, July 29-31, 1918, and at St. Thibaut, France, August 6-12, 1918. Accompanying his battalion in the attack on Sergy, he advanced for more than a mile under heavy shell fire, and as soon as the southern half of the town had been taken he established his dressing station, maintaining it during the three days of fighting under constant and severe bombardment. When his battalion went into action at St. Thibaut this faithful officer again displayed heroic devotion to duty by working in his dressing station under the most trying conditions for six days while the town was bombarded with gas and high explosive shells.

LEO J. CRUM, Lieut., M. C., U. S. Army, 126th Infantry, Kalamazoo, Mich. For extraordinary heroism in action near Cierges, France, July 31 and August 1, 1918. During the attack against Cierges by his regiment he worked continuously and heroically under fire to treat and evacuate the wounded. When the house in which his first-aid station was located was struck by an enemy shell he safely evacuated all of his patients and promptly established another aid station near the front. His untiring efforts and personal bravery saved the lives of many wounded and suffering men and were a source of inspiration to the entire command.

FRANK L. WILLIAMS, Lieut. M. C., U. S. Army, 168th Infantry, Des Moines, Ia. For extraordinary heroism in action in Champagne, east of Reims, France, July 15, 1918, and near the River Ourcq, northeast of Chateau-Thierry, France, July 30, 1918. He voluntarily left a dugout on the Champagne front, and for more than two hours, all the time under shell fire, administered to the needs of wounded men who were lying in the open. During the advance across the River Ourcq he voluntarily remained in exposed positions under heavy shell fire, caring for and dressing the wounded, until he was severely injured.

GEORGE H. GAGE, Capt., M. C., U. S. Army, 28th Infantry, Rochester, N. Y. Conspicuous for his courage in the actions at Rambucourt on March 17, 1918, and at Cantigny, May 28, 1918, he gave inspiration to the officers and men of the command by his extraordinary heroism throughout the operations south of Soissons, July 18 to 22, 1918, and especially at Berzy-le-Sex, July 21, 1918, when he accompanied the first line and attended the wounded in the open under incessant machine gun and artillery fire.

FREDERICK W. BLACK, Capt., M. C., U. S. Army, 28th Infantry, Punxsutawney, Pa. For extraordinary heroism in action near Soissons, France, July 18-22, 1918. He went over the top to the attack in the first wave and was wounded on the morning of the first day. Disregarding his wound, he pressed on with the attacking troops and crossed and recrossed the sector immediately behind the most advanced wave, rendering first aid to wounded and placing them in shell holes. He worked unceasingly without sleep or rest and was again wounded on the fourth day by shell fire. Though twice wounded, he steadily refused to be evacuated until the evening of the fourth day, when he was exhausted and suffering from his wounds.

HONORABLE DISCHARGES, MEDICAL CORPS, U. S. ARMY

Note.—In the following list, L., signifies lieutenant; C., captain; M., major; L. C., lieutenant-colonel; Col., colonel, and B. G., brigadier-general.

To Jefferson Barracks, Mo., from Northeastern Department, Lieut. S. B. BUCK, Anderson; from West Baden, Lieut. T. E. LILLY, Kansas City.

To Philadelphia, Pa., from Camp Zachary Taylor, Major E. G. MARK, Kansas City.

To Pittsburgh, Pa., from Camp Dodge, Lieut. G. W. GAINES, Rayville; Capt. W. T. HIRSCHI, St. Louis.

To Rockefeller Institute for instruction in the treatment of infected wounds, and on completion *to Jefferson Barracks,* from Camp Pike, Lieut. H. J. BLOUNT, Potosi.

Montana

To Biltmore, N. C., from Camp Meade, Lieut. G. A. LEWIS, Roundup.

To Camp Meade, Md., base hospital, from Army Medical School, Capt. A. G. FULLER, Missoula.

Nebraska

To Camp Dodge, Iowa, base hospital, from Fort Snelling, Lieut. R. L. IVINS, Crawford.

To Chicago, Ill., from Camp Grant, Capt. C. L. FAHNESTOCK, McCook.

To El Paso, Texas, from Camp Owen Bierne, Lieut. C. W. PARKS, Lincoln.

To Fort Sheridan, Ill., from Camp Custer, Capt. D. C. HILTON, Lincoln.

To Jefferson Barracks, Mo., from St. Louis, Capt. F. C. GENUNG, Wausa.

To Oteen, N. C., from Camp Joseph E. Johnston, Capt. J. F. ALLEN, Omaha.

New Hampshire

The following order has been revoked: *To Scituate, Mass.,* from Penniman, Va., Capt. W. P. CRAIG, Walpole.

New Jersey

To Colonia, N. J., from Camp Sherman, Lieut. H. B. EPSTEIN, Newark.

To Fort McHenry, Md., from Rochester, Capt. C. B. LUFBURROW, Plainfield.

To Hoboken, N. J., from Camp Dix, Capt. S. L. SALASIN, Atlantic City.

To Hot Springs, Ark., from Camp Dix, Col. R. M. CULLER.

To Washington, D. C., St. Elizabeth's Hospital, from Camp Gordon, Capt. D. E. WARREN, Passaic.

To Whipple Barracks, Ariz., from San Antonio, Capt. W. H. HAINES, Audubon.

New Mexico

To Denver, Colo., from Fort Bayard, Lieut. A. D. LAZENBY.

New York

To Army Medical School, from Fort Oglethorpe, Capt. J. C. TEAS, Flushing. For instruction, Major R. R. FITCH, Rochester; from Camp Dix, Major W. W. PLUMMER, Buffalo.

To Camp Custer, Mich., from Camp Dix, Capt. B. A. HALL, Oxford.

To Camp Dix, N. J., to examine the troops for cardiovascular diseases, from Lakewood, Lieut. A. EBERLE, Brooklyn.

To Camp Grant, Ill., from Camp Dodge, Capt. T. A. ROGERS, Plattsburg.

To Camp Knox, Ky., from Camp Greene, Major R. B. BONTECCOU, Ithaca.

To Camp Meade, Md., base hospital, from Camp Lee, Lieut. F. E. DUBOIS, New York.

To Camp Pike, Ark., from Camp Bowie, Lieut. F. N. POTTS, Buffalo.

To Camp Sherman, Ohio, from Camp Gordon, Lieut. A. TOWBIN, New York.

To Camp Travis, Texas, from Fort Sam Houston, Lieut. A. RAVICH, Brooklyn.

To Camp Upton, N. Y., base hospital, from Camp Abraham Eustis, Lieut. H. C. DORSEY, New York.

To Camp Zachary Taylor, Ky., to examine the troops for cardiovascular diseases, from Lakewood, Lieut. A. C. HERRING, New York.

To Carlisle, Pa., from Lakewood, Lieut. F. W. BISHOP, New York.

To Colonia, N. J., from Camp Dix, Lieut. S. W. HAUSMAN, Ogdenburg; from Fort Oglethorpe, Lieut. J. G. HART, Rochester.

To Columbia Barracks, Ohio, from Denver, Capt. H. A. CRAIG, Staten Island.

To Eastview, N. Y., from Camp Devens, Lieut. V. A. NARDIELLO, New York.

To Fort McHenry, Md., from Mineola, Capt. J. M. WHEELER, New York.

To Fort Ontario, N. Y., from Camp Dodge, Capt. B. R. NAIRN, Buffalo.

To Fort Snelling, Minn., from Camp Dix, Major E. L. HANES, Rochester; from Camp Dodge, Lieut. B. M. KULLY, New York.

To Garden City, N. Y., from Camp Dix, Lieut. D. D. STOWELL, New York.

To Hoboken, N. J., from Camp Dix, Major W. D. ALSEVER, Syracuse; Capt. A. F. WRIGHT, Wayne; Lieut. J. J. KILCOURSE, Jamaica; from Washington, Capt. A. W. KLEIN, New York.

To Newport News, Va., from Fort Oglethorpe, Lieut. C. B. GIBSON, New York.

To Otisville, N. Y., from Syracuse, Lieut. B. R. KELLY, New York.

To Philadelphia, Pa., from Camp Gorden, Lieut. W. H. CONKLIN, New York; from Camp Wheeler, Capt. C. W. FIELD, New York.

To Plattsburg Barracks, N. Y., from Camp Joseph E. Johnston, Capt. L. A. WING, New York.

To report to the commanding general, Western Department, from Camp Fremont, Lieut. P. E. McCHESNEY, New York.

To Rockefeller Institute for instruction in the treatment of infected wounds, from Camp Greene, Lieut. C. W. DEMONG, Syracuse. On completion *to his proper station,* from Camp Devens, Lieut. L. A. WYLIE, Harrison.

To Syracuse, N. Y., from Camp McClellan, Lieut. L. L. SHAPIRO, New York.

To Walter Reed General Hospital, from Camp Meade, Lieut. H. E. WHEELOCK, Fredonia; from *Fort Oglethorpe,* Capt. G. V. JOHNSON, Schenectady.

To Washington, D. C., Col. H. H. M. LYLE, New York; from Camp Dix, Col. J. F. McKERNON, *New York.* Surgeon-General's Office, from Camp Dix, Lieut.-Cols. R. DERBY, W. J. ELSER, New York; from Plattsburg *Barracks,* Lieut.-Col. T. D. WOODSON.

To Williamsbridge, N. Y., from Camp Dix, Major L. G. COLE, New York.

The following order has been revoked: *To Boston, Mass.,* from Camp Crane, Lieut. G. G. DAVIS, Arcade.

North Carolina

To Camp Gordon, Ga., base hospital, Lieut.-Col. J. W. LONG, Greensboro.

To Camp Travis, Texas, as tuberculosis examiner, *from* Camp Logan, Lieut. W. T. LONG, Roxboro.

To East Potomac Barracks, D. C., from Camp Lee, Lieut. W. C. PETERSON, Wilmington.

To Markleton, Pa., from Camp Sheridan, Lieut. M. R. GIBSON, Raleigh.

To Oteen, N. C., from Washington, D. C., Lieut. W. C. PETERSON, Wilmington.

North Dakota

To Fort Keogh, Mont., from Camp Lewis, Capt. A. M. FISHER, Bismarck.

To Fort Snelling, Minn., from Fort Riley, Lieut. W. C. AYLEN, Mandan.

Ohio

To Army Medical School, from Camp *Dix,* Lieut. C. W. MAXSON, Steubenville.

To Camp Meade, Md., base hospital, from Camp Dix, Capt. N. L. ZINNER, Cleveland.

To Colonia, N. J., from Army Medical School, Capt. L. B. ZINTSMASTER, Massillon.

To Dallas, Texas, Love Field, from Austin, Lieut. F. S. VAN DYKE, Columbus.

To Fort Snelling, Minn., from Camp Dodge, Lieut. C. G. McPHERSON, Xenia.

To Hoboken, N. J., from Camp Dix, Lieut.-Col. C. R. CLARK, Youngstown.

To Philadelphia, Pa., from Camp Gordon, Lieut. A. H. BERR, Cleveland.

Oklahoma

To Army Medical School, from Camp Dix, Lieut. C. C. SHAW, McAlester.

To Fort Sam Houston, Texas, from Camp MacArthur, Lieuts. I. C. MORRIS, Cushing; P. C. CHRISTIAN, Oklahoma City.

To Hot Springs, Ark., from Camp *Abraham* Eustis, Major R. L. KURTZ, Nowata.

Oregon

To San Francisco, Calif., Letterman General Hospital, from Camp Dix, Major T. M. JOYCE, *Portland;* from *Philadelphia,* Lieut. A. O. WALLER, Eugene.

Pennsylvania

To Army Medical School, from Fort Oglethorpe, Lieut. C. W. WAKEFIELD, Pittsburgh.

To Camp A. A. Humphreys, Va., from Camp Jackson, *Major* A. E. DAVIS, Scranton.

To Camp Abraham Eustis, Va., from Camp Dix, Capt. W. J. DOYLE, Wilkes-Barre.

To Camp Dix, N. J., base hospital, from Fort Sheridan, Capt. S. J. *REPPLIER, Philadelphia.*

To *Camp Jackson, S. C.,* from Camp Crane, Major F. R. SHUTE, Philadelphia.

To Camp Lee, Va., from Hampton, Va., Lieut. W. S. TAYLOR, Harrisburg.

To Camp Sherman, Ohio, base hospital, from Camp Dix, Major J. D. ELLIOTT, Philadelphia.

To Camp Zachary Taylor, Ky., base hospital, from Army Medical School, Capt. L. H. MAYER, Jr., Johnstown.

To Denver, Colo., from Fort Sill, Capt. H. O. MATTER, Pittsburgh.

To Fort Des Moines, Iowa, from Fort Oglethorpe, Lieut. W. C. CHANEY, *Philadelphia.*

To Fort McHenry, Md., from Boston, Lieut. E. H. THOMPSON, *Philadelphia.*

To Hoboken, N. J., from Camp Dix, Lieut.-Cols. W. H. WALSH, Philadelphia; J. D. HEARD, Pittsburgh; from Camp Meade, Lieut. G. W. A. HESS, Philadelphia; from Long Beach, Lieut. D. L. SIMON, Pittsburgh.

To Lakewood, N. J., from Camp Upton, Lieut. L. N. GAY, Shamokin; from Camp Zachary Taylor, Lieut. T. M. MABON, Pittsburgh.

To Philadelphia, Pa., from Camp Dix, Capt. J. E. ELLINGER, Philadelphia; from Camp Gordon, Capt. J. BEATTIE, Lebanon; from Fort McPherson, Lieut. W. C. ELY, Philadelphia.

To Pittsburgh, Pa., from Carlisle, Pa., Lieut. J. W. FISHER, Pittsburgh.

To Washington, D. C., Surgeon-General's Office, from Camp Dix, Majors H. W. CATTELL, Philadelphia; R. E. DAVISON, Pittsburgh.

Philippine Islands

To San Francisco, Calif., Capt. A. P. GOOFF, Manila; from Philippine *Department,* Major J. M. PRATT.

Rhode Island

To Rockefeller Institute for instruction in the treatment of infected wounds, and on completion *to his proper station,* from Camp Dix, Lieut. E. M. PORTER, Providence.

South Carolina

To Fort McPherson, Ga., from Fort *Oglethorpe,* Lieut. J. D. GUESS, Charleston.

To Lakewood, N. J., from Washington, Capt. T. C. GALLOWAY, Columbus.

Tennessee

To Camp Devens, Mass., base hospital, from Camp Hancock, Capt. R. L. SANDERS, Memphis.

To Camp Gordon, Ga., as tuberculosis examiner, from Camp Logan, Lieut. M. L. CONNELL, Nashville.

To Camp Upton, N. Y., from Camp Dix, Lieut. C. O. BAILEY, Memphis. Base hospital, *from* Camp Dix, Capt. J. W. MORRIS, Sommerville.

To Fort Logan H. Roots, Ark., from Camp Pike, *Lieut.* O. P. WALKER, Memphis.

To Montgomery, Ala., from Americus, Ga., Lieut. E. C. SEALE, Nashville.

To Oteen, N. C., from Camp Gordon, Capt. O. S. DEATHRIDGE, Nashville.

Texas

To Army Medical School for instruction, from Camp Dix, Major C. S. VENABLE, San Antonio.

To Camp Beauregard, La., from Fort Oglethorpe, Lieut. J. W. McKEE, Houston.

To Camp Kearney, Calif., to examine the command for cardiovascular diseases, from Camp Lewis, Lieut. R. L. ROSS, *San Antonio.*

To Camp Logan, Texas, base hospital, from Camp Upton, Lieut. R. A. THARP, Austin.

To Camp Meade, Md., base *hospital,* from Boston, Lieut. H. K. MORRISON, Houston. *To examine the troops* for cardiovascular diseases, from Fort Oglethorpe, Lieut. E. TOOMIN, Waco.

To Camp Travis, Texas, base hospital, from Camp Dix, Capt. H. M. BUSH, San Antonio.

To Fort San Houston, Texas, from Camp John Wise, Capt. C. F. HAYES, Fort *Worth; from* Camp MacArthur, Lieuts. W. J. MASTERS, Knox City; J. E. HAMMOND, *Munday;* H. A. WINTER, Port Arthur. Base hospital, from Camp Logan, *Capt.* A. S. *LOVE,* Ballinger.

To Jackson Barracks, La., from Camp Travis, Lieut. B. H. PALMER.

To Newport News, Va., from Camp Abraham Eustis, Capt. W. V. PRUETT, *Brownsville.*

Utah

To Fort Douglas, Utah, from Camp Lewis, Capt. C. M. BENEDICT, Salt Lake City; from Logan, Utah, Major W. CHRISTOPHERSON, Salt Lake City.

The following order has been revoked: *To Fort Des Moines, Iowa,* from Fort Riley, Lieut. F. F. HATCH, Salt Lake City.

Vermont

To Camp Upton, N. Y., from Detroit, Capt. N. J. DELEHANTY, Rutland.

To Newport News, Va., from Boston, Lieut. H. L. PIERCE, Swanton.

To Philadelphia, Pa., from Camp Dix, Lieut. R. L. MAYNARD, Burlington.

Virginia

To Newport News, Va., from Camp Bragg, Capt. C. T. PEIRCE, Litwalton.

To Philadelphia, Pa., from Camp Devens, Major H. FLETCHER, Fairfax.

Washington

To Camp A. A. Humphreys, Va., as camp sanitary inspector, from Fort Riley, Capt. W. H. AXTELL, *Bellingham.*

To Camp Lee, Va., from Fort Oglethorpe, Lieut. C. R. GLENN, Kelso.

To Fort Caswell, N. C., from Camp MacArthur, Capt. A. E. HENBY, Seattle.

To Garden City, N. Y., from Camp Dix, Major R. W. PERRY, Seattle.

To Hoboken, N. J., from Camp Dix, Capt. W. W. HARRINGTON, Spokane.

To San Francisco, Calif., from Vancouver Barracks, Major R. A. ALLEN, Tacoma; Capts. E. W. COX, Monroe; H. B. CLOUGH Tenasket.

Wisconsin

To Camp Dodge, Iowa, base hospital, from Fort Riley, Major W. T. CLARK, Fort Atkinson. *To examine the command* for cardiovascular diseases, from Lakewood, Lieut. B. F. KOCH, Wauwatosa.

To Camp Grant, Ill., from Camp Lewis, Lieut. L. M. PEARSON, Tomahawk; from Newport News, Va., Lieut. J. F. SCHNEIDER, Oshkosh.

To Fort Des Moines, Iowa, from Camp Upton, Lieut. A. YAFFE, Milwaukee.

To Fort Sam Houston, Texas, from San Antonio, Capt. C. H. MEYST, Burlington.

To Fort Sheridan, from Camp Cody, Capt. C. O. DECKER, Crandon.

To Fort Snelling, Minn., from Fort Oglethorpe, Capt. R. W. JONES, Wausaw.

To Oteen, N. C., for instruction, from Camp Joseph E. *Johnston,* Capt. B. F. HOYT, South Kaukauna.

To Rockefeller Institute for instruction in the treatment of infected wounds, and on completion *to his proper station,* from Camp Custer, Lieut. I. E. LEVITAS, Green Bay.

Wyoming

To Fort D. A. Russell, Wyo., from Camp Dodge, Capt. L. P. DESMOND, Cheyenne.

ORDERS TO OFFICERS OF THE UNITED STATES PUBLIC HEALTH SERVICE

Asst. Surg.-General L. L. LUMSDEN, relieved from duty at St. Louis, Mo., and continued on present duty as chief of the division of Hygiene and Sanitation, Emergency Fleet Corporation, Philadelphia, Pa.

Senior Surg. G. M. MAGRUDER, relieved at *Portland,* Oregon, and Tacoma, Wash., proceed to Memphis, Tenn, for duty at the *Marine* Hospital.

Senior Surg. A. J. LANZA, relieved at Pittsburgh, Pa., continued on duty at Washington, D. C., in connection with the Division of Industrial Hygiene and Medicine.

Surgeon FRIENCH SIMPSON, orders to *Fort Stanton revoked.* Proceed to San Francisco Quarantine Station for duty.

Passed Asst. Surg. L. O. WELDON, relieved at Lawton, *Okla.,* detailed for duty with the Division of Venereal Diseases, *Washington,* D. C.

Passed Asst. Surg. J. G. WILSON, proceed to Chicago, Ill., for duty *on board of inspection* of the Speedway Hospital.

Passed Asst. Surg. O. H. COX, relieved at Jacksonville, Fla., proceed to Pensacola, Fla., for duty in connection with extracantonment sanitation.

Asst. Surg. L. L. WILLIAMS, JR., proceed to Wilmington, N. C., for conference on antimalarial measures.

Acting Asst. Surg. R. D. CLIPPINGER, proceed to Harrisburg, Pa., for duty in connection with influenza control.

Acting Asst. Surg. E. B. LIDDELL, proceed to Houston, Texas, for duty in clinic.

Acting Asst. Surg. E. W. SCOTT, proceed to Kansas City, Mo., for conference concerning influenza control.

Acting Asst. Surg. M. E. STEINBERG, proceed to Hansford, W. Va., to investigate outbreak of influenza.

Scient. Asst. M. B. HULL, proceed to New Haven, Conn., for intensive studies of industrial sanitation.

Scient. Asst. LLOYD R. JONES, relieved at Charlotte, N. C., proceed to Fayetteville, N. C., for duty in connection with extracantonment sanitation.

Scient. Asst. H. B. LARNER, proceed to Cullman, Alabama, for duty in outbreak of Smallpox.

Scient. Asst. JOHN B. WEBB, relieved at Waco, Texas, proceed to Portsmouth, Va., for duty in extracantonment sanitation.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST; SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION, PUBLIC HEALTH, ETC.)

ALASKA

Irregular Practitioner Convicted.—A drugless healer by the name of A. M. Brevick of Ketchikan, it is reported, was arrested recently by the Board of Medical Examiners of Alaska and, January 27, pleaded guilty of practicing medicine without license, and was fined $50 and costs.

DISTRICT OF COLUMBIA

Personal.—Dr. Tom A. Williams, Washington, has returned from France after an absence of eighteen months, during which time he acted as medical adviser to the bureau of medical research of the American Red Cross.

ILLINOIS

Personal.—THE JOURNAL has received word of the arrival and active work of the American Red Cross Commission to Greece, at Athens, headed by Deputy Commissioner Major Carl E. Black.

Restoration of License Refused.—The Department of Registration and Education of the State of Illinois, February 1, gave a rehearing to Dr. Frank J. Oshay, Ladd, whose license to practice medicine and surgery in Illinois was revoked, Dec. 9, 1918; but after rehearing confirmed its previous action.

Medical Examiners Reappointed.—Mr. Francis W. Shepardson, director of the Department of Registration and Education, has reappointed, as the medical examining committee for 1919, Drs. John A. Robinson, William L. Noble and Guy M. Cushing, Chicago; Dr. Lewis C. Taylor, Springfield, and Dr. Jonathan L. Wiggins, East St. Louis.

Chicago

Institute of Medicine Meeting.—The Institute of Medicine of Chicago will have a symposium on influenza, February 21, at the City Club, at 8 o'clock. The subjects announced are: "Epidemiology," Prof. E. O. Jordan; "Bacteriology," Dr. David J. Davis; "Pathologic Anatomy," Dr. Edwin R. LeCount; "In Military Camps," Dr. Walter W. Hamburger; "Clinical," Dr. Solomon Strouse, and "Public Health," Dr. Heman Spalding.

Personal.—Dr. Joseph C. Beck, who has been in the charge of the Czecho-Slovac Hospital at Convak, France, has been transferred to Prague, Bohemia, where he is working in reconstructive and plastic surgery of the head and neck.——John G. O'Malley, Capt., M. C., U. S. Army, has returned after more than three years service abroad, first with the Royal Army Medical Corps, and later in the Medical Corps, U. S. Army.——George C. Tallerday, Capt., M. C., U. S. Army, who has been with the American Army of Occupation in Coblenz, has returned from abroad.

INDIANA

Communicable Diseases.—It is reported that there are now twenty-three cases of smallpox in Elkhart, and the situation is showing no improvement.——Diphtheria is reported to be prevalent in Columbia City.

Personal.—Dr. Zera M. Beaman, for several years secretary of the board of health of North Manchester, has resigned.——Dr. Lyman K. Gould has been appointed consulting surgeon to the Wabash Railroad at Fort Wayne, to succeed Dr. Edward J. McOscar, deceased.——Dr. John W. Bilderback has been appointed health officer of New Haven.

IOWA

Personal.—Dr. George E. Decker, Davenport, has been elected a director of the Davenport Commercial Club.

Hospital Notes.—The new Children's Hospital, which is being constructed in Iowa City at a cost of $150,000, is nearing completion. This building will be given over entirely to the care of crippled children.——The State Hospital for Epileptics, Woodward, was recently dedicated with Governor Harding and State Red Cross Director Kepford as principal speakers.

KANSAS

Appropriation Asked.—The state board of administration has been asked for an appropriation of $200,000 for a medical school at Rosedale.

Personal.—Dr. James S. Rushton, Morrill, was operated on recently for appendicitis in a base hospital at Kelly Field, San Antonio, Texas, and is reported to be doing well.

Memorial Hospital Suggested.—As a tribute to the memory of Dr. William Thomas Fitzsimmons, the first American medical officer to be killed during the war, the Kansas State Medical Society proposes to enlarge the Bell Hospital, Rosedale, and rechristen it the Fitzsimmons Memorial Hospital.

MARYLAND

Personal.—Seven Baltimore physicians and surgeons who have been overseas as members of the Johns Hopkins and the University Hospital units arrived in New York, February 1. All were ordered to report at Camp Dix, N. Y., where they will be held pending further orders. The officers are: Majors Walter A. Baetjer, George J. Heuer, Charles Bagley, Jr., Cary B. Gamble, Jr., Capt. William H. Smith and Lieuts. Henry Shaw and R. G. Coblentz.

Convention of Health Boards.—Ways and means of protecting the public health and building up a stronger generation were discussed at a convention of the health boards of Maryland, called by the state board of health, and held at the Medical and Chirurgical Faculty Building, Baltimore, February 14 and 15. Dr. John A. Farrell of the International Health Board, and director of its work in the United States, delivered a lecture at the opening session on "The Organization of Public Health Work in the Counties." The lecture was preceded by papers by the chiefs of divisions of the state department of health giving accounts of the organizations: bacteriology, Dr. William Royal Stokes; vital statistics, Dr. Frederick V. Beitler; sanitary engineering, Robert B. Morse; chemistry, Dr. Wyatt W. Randall; food and drugs, Dr. F. C. Blanck, and communicable diseases, Dr. C. Hampson Jones. Tuberculosis was a most important subject under discussion at the afternoon session and W. H. Sawyer, Major, Medical Corps, U. S. Army, discussed prevention and control of social diseases, and was followed by Dr. Allan W. Freeman, health officer of Ohio, who spoke on "Local Public Health Administration in the States." The School of Hygiene at the Johns Hopkins University was also visited. At the evening session Dr. William H. Welch, president of the state board of health and director of the Johns Hopkins School of Hygiene, addressed the conference, and was followed by Allan J. McLaughlin, assistant surgeon-general, U. S. P. H. S., who delivered an address on "Public Health Administration and Organization."

NEW JERSEY

Health Officials Elect Officers.—At the annual conference of New Jersey Health Officials held in Trenton, January 25, Henry V. Ammerman, Kearny, was elected president, Dr. Talbot Reed, Atlantic City, vice president, and R. Chandler, Plainfield, was reelected secretary and treasurer.

NEW YORK

Bill to Legitimatize War Babies.—A bill introduced into the New York Legislature, February 4, by Mrs. Mary M. Lilly, representing the Seventh Assembly District of Manhattan, and advocated by Judge Robert J. Wilkin of the Children's Court of New York City, provides for the legitimatization of so-called war babies, which, according to reports, are more numerous than is imagined. The bill provides that the identity of the father must be established *in* a court of law, and is so framed that designing women cannot resort to the law for purposes of blackmail.

Physicians for Rural Communities.—The state department of health asserts that many rural communities in New York state have been without physicians because of death, permanent military appointments or other causes. As a result of letters received from a number of such communities, the state department of health has undertaken to put the authorities in such places in touch with physicians desiring rural locations. This has been accomplished by advertisements in the medical journals and newspaper publicity. Replies have been received from ninety-six physicians located in twenty different states, and names have been sent to twenty-four communities.

New York City

Deaths from Violence.—Approximately 5,200 persons met violent deaths in New York City during 1918, according to the annual report of the chief medical examiner (coroner). Of these 772 were suicide, 273 were homicide. A slight decrease as compared with 1917.

Personal.—Dr. S. Dana Hubbard has been placed temporarily in charge of the division of industrial hygiene by the health commissioner.——Alexis Carrel, Major, M. C., U. S. Army, who has been serving with the French army in the Montdidier section, returned on the Transatlantique steamer *La Lorraine*, January 28, and began to resume his work at the Rockefeller institution for medical research.

The Health Department and the Drug Evil.—In addressing the Federation of Women's Clubs, February 7, Health Commissioner Dr. Royal S. Copeland stated that there are at present 200,000 drug addicts in the city of New York and that there are 2,600 retail drug stores. One drug store sold 585 ounces of narcotics in December. Dr. Copeland states that the health department is going to establish drug stations and check up narcotic sales.

Maternity Center Association Meets.—At the annual meeting of this organization, held recently, it was announced that the association had established twenty-two clinics and had at present 7,400 expectant mothers under its care. Dr. Henry Dwight Chapin, in an address before the association, stated that 700 women died in childbirth in this city last year. The association adopted resolutions endorsing the health insurance bill now before the legislature.

Motor Fatalities Break Record.—The report of the National Highways Protective Society for the month of January shows that forty-nine persons were killed by automobiles in New York City during the month, eight were killed by surface cars, and one by a wagon, making fifty-eight in all, which is the highest number of fatalities yet recorded for the month of January. The figures for the year 1918 show an increase of fatalities from automobiles of 30 per cent. over 1917, with 1,189 killed, as against 837 for 1917. Basing the value of a human life on the estimate of the federal government, which insures a soldier's life at $10,000, the economic loss represented by these accidental deaths is $11,890,000.

Medical Examiner Versus Coroner.—The annual report of the chief medical examiner, Dr. Charles Norris, for the first year of his office which succeeded that of the coroners' system has just been made public. It amply demonstrates the advantages of this system over the old coroners' system. The report shows that, whereas the budget for the year of the coroners' system (1917) was $158,000, that for the medical examiner for the first year was $92,000, the latter sum including laboratory work of the greatest value. The report reveals that the number of homicides during 1918 was 273, against 283 in 1917. There was an increase of more than fifty in deaths from accidental poisoning. In all probability this is due to the more scientific examination to determine the cause of death. The report discloses that the method of suicide most frequently used is by illuminating gas, 311 persons in the greater city having chosen that method during the past year. The second in frequency on the suicide list was jumping from a building, 119 having sought death in this way. Shooting was the means of self-inflicted death in ninety-two instances and hanging in eighty-eight. Of 125 accidental deaths, forty were due to morphin, heroin, opium and cocain. There were in all 526 accidental deaths due to illuminating gas, an increase of twenty-five over the previous years. The medical examiner's office has under consideration recommendations for having commercial poisons, such as those for the extermination of rats and insects, put up in packages that show their deadly nature, since many persons died during the year because they mistakenly took what they thought was medicine from packages containing pure poison.

OHIO

Cleveland Physicians Prosecuted.—The Ohio State Medical Board reports that Dr. John L. Hoyer of Cleveland, whose license was revoked in 1899 *for felony*, was recently convicted in the police court and sentenced to thirty days in jail for the illegal practice of medicine.——Dr. Jay Boyd is under arrest for illegal practice. Dr. Boyd's Ohio license was revoked, July, 1899, because of extravagant advertising.——Dr. George C. Halliday, claiming to be a graduate of Harvard, was arrested for the illegal practice of medicine and was released on the bond of $1,000. He has left the state, forfeiting his bond.

Licenses Revoked.—At its meeting, January 29, the Ohio State Medical Board revoked the license of Dr. Levi White Hunt of Toledo for alleged extravagant advertising having a tendency to deceive and defraud the public. Dr. Hunt has appealed the case to the Common Pleas Court.——At a special meeting, January 21, the board revoked the license of William H. Stukenholt of Cleveland for having association with and lending his name to an illegal practitioner of medicine.——January 21, the board also revoked the license of Herbert E. Edwards of Cleveland. Dr. Edwards had previously been convicted in the federal court for misbranding pharmaceutical preparations and had been sentenced for eighteen months in the federal prison at Atlanta. This decision was but recently confirmed by the supreme court.——The license of Charles B. Weedman of Cleveland was also revoked, January 21, for gross immorality—conviction of the illegal sale of narcotics—and lending his name or having connection with an illegal practitioner of medicine. The evidence showed Dr. Weedman had received $40 per week from the "United Doctors" which investigation showed was owned by Dr. John P. Furno, Detroit, who was not licensed to practice in Ohio.

PENNSYLVANIA

Philadelphia

Women's Hospital Drive.—The women campaigners who are seeking to raise $75,000 for the West Philadelphia Hospital for Women had only $15,000 to gain to reach their goal on February 8, the last day of the campaign.

Personal.—Dr. Richard P. Smith has been named assistant medical inspector of the board of health.——Dr. Mulford K. Fisher, who was taken ill with croupous pneumonia while attending the convention of roentgenologists at Atlantic City, N. J., is now convalescent.

Friends Plan Hospital.—A hospital under the Society of Friends, provided for in the will of the Jeans who died twelve years ago, may soon be built as there is $2,000,000 available for this purpose. The proposed hospital will be for the treatment of cancerous and nervous diseases and will be located within 20 miles of Philadelphia.

Medical Inspectors Resign.—Forty medical inspectors of the public schools resigned in a body, February 7, resignation to become effective March 1, because they are unwilling to longer work for $600 a year. The director of health and charities has asked the inspectors to delay action pending action by the board, but since they had resigned he could do nothing else but appoint others in their places.

College of Physicians.—At the stated meeting of the College of Physicians of Philadelphia, held February 5, the scientific portion of the meeting was devoted to papers on "Concussions and Injuries of the Eye and Warfare," by Dr. George E. deSchweinitz; "Reeducation of the Blind," by James Bordley, Jr., Lieut.-Col., M. C., U. S. Army; "Research Work on the Problems of Aviation," by Walter B. Lancaster, Major, M. C., U. S. Army, and the "Army School of Ophthalmology," by Meyer Wiener, Major, M. C., U. S. Army.

Officers Elected.—At the stated meeting of the Obstetrical Society of Philadelphia, held at the College of Physicians, February 16, the following officers were elected: president, F. Hurst Maier; vice presidents, Stephen E. Tracy and Alfred Heineberg; secretary, Edward A. Schumann; secretary pro tem, Charles S. Barnes, and treasurer, William E. Parke.——The Philadelphia Clinical Association, February 3, elected the following officers: president, William Duffield Robinson; vice president, Edward J. Moore; secretary, Charles S. Barnes, and treasurer, William McKeage.

CANADA

Influenza.—With thirty deaths reported to date, the number of new cases of influenza in the province of Quebec in 100 of the 2,500 municipalities, is put down at 2,000. Dr. Elzear Pelletier, provincial officer of health of Quebec, states that the present is a mild epidemic compared with that of last fall. The schools which escaped the epidemic last fall seem now to be suffering more. The first epidemic in 1918 caused 13,880 deaths, and 530,700 cases of the influenza.

Disciplinary Power Asked.—The Ontario Medical Council will seek power from the Ontario legislature to discipline its members when such action is necessary in connection with breaches of the Ontario Temperance Act. During the last few months there have been several convictions of doctors for violations of the Ontario Temperance Act; and the executives of the council have felt these members should be dealt with, but doubt as to the authority of the council prevented action.

Municipalities to Be Liable.—The liberal caucus of the Quebec legislative body discussed recently the contributions by municipalities to hospitals and other institutions for patients from their districts treated in the hospitals of Montreal and other big cities of the province. As a result a bill will be introduced in the legislature which will make those municipalities liable for a portion of the cost of treatment, in the same manner as they now pay for the maintenance and treatment of patients in the hospitals for the insane in that province.

Osteopaths in Quebec.—The osteopaths have a bill before the Quebec legislature. Dr. A. Edmond Burrows, Montreal, has a letter in the public press stating that the bill is a challenge to the educative system of Canadian universities. *He claims* that the opposition to the bill from physicians and surgeons is in order to protect the welfare of the people, and to maintain the high standard of the medical profession in Canada. In his opinion any trained masseur or masseuse is capable of administering the treatment termed "*osteopathic*," but it requires a trained physician to prescribe when such treatment is beneficial or when it would be harmful. The passing of such a law would open a back door for the admittance into the medical profession of unqualified persons.

Personal.—Capt. Robert D. Moyle of the Second Field Ambulance of the C. A. M. C. has been awarded the Military Cross "for conspicuous courage and devotion to duty." He is a graduate in arts of McMaster University, Toronto, and of Johns Hopkins University in medicine.——Dr. Robert J. Manion, M.P., Fort William, Ont., will second the address in reply to the speech from the throne in the Canadian House of Commons when the session opens, February 20.——Dr. L. de Lotbiniere, Montreal, was the guest of honor at a banquet held in that city, February 5. There were 200 French and English citizens present, including many medical men. The occasion was the appointment of Dr. Lotbiniere to the deanship of the Medical Faculty of Laval University, in succession to the late Dr. Emmanuel P. Lachapelle. Dr. Rodolphe Boulet, Montreal, was in the chair.

Social Hygiene Laws for Canada.—During the week ended February 8, a conference was held at Ottawa, called at the instance of Sir Thomas White, the acting prime minister of Canada, to consider laws for the prevention and treatment of the venereal diseases in Canada. Among others present were Major-Gen. John T. Fotheringham, C.M.G., Ottawa; Dr. J. Alexander Hutchison, Montreal, president of the Canadian Public Health Association; Dr. Maurice M. Seymour, chief officer of health of *Regina, Saskatchewan*; Dr. Gordon Bell, health officer of Winnipeg, Manit.; Col. John W. S. McCullough, Toronto, and Dr. George G. Melvin, medical officer of health, New Brunswick. A department of health for the dominion; compulsory notification and compulsory treatment of the venereal diseases in every *province*; penalties for evading the laws; prevention of quack advertising, treatment and medicines; cancellation of the monopoly in the *special* products for syphilis, and the granting of permission to conduct such manufacture under the special supervision of the board of health of each province, and the rendering of financial assistance by the dominion government to the provinces in fighting the venereal diseases, were the chief topics of discussion.

GENERAL

Public Health Service Appeals to Physicians for Cooperation in Fight Against Venereal Diseases.—Physicians are receiving notices from the public health service relative to the prevention and treatment of venereal disease. In order to secure cooperation from the medical profession those interested are asked to return a postal card on which they give assurance of cooperation ir [illegible] ses, securing prompt treatment for them . [illegible] literature relative to the spread of venereal infection.

Hope for Blind.—"Victory Over Blindness" was the title of an address by Sir Arthur Pearson, the blind founder and director of St. Dunstan's Hotel for Blinded Soldiers, London, England, before a mass meeting at the Century Theater in New York City, February 4. Sir Arthur described his work in restoring blinded British soldiers to self-support. Lieut.-Col. James Bordley, Baltimore, in charge of work for blinded American soldiers and sailors and director of the Red Cross Institute for the Blind, told of the work being done at Evergreen, Baltimore, for men of the American Expeditionary Force who lost their sight in action. The meeting was presided over by Douglas C. McMurtrie, director of the Red Cross Institute for Crippled and Disabled Men, under the auspices of which organization the meeting was held.

Opportunities for Trained Sanitarians.—The threatened recurrence of influenza next year is causing many communities to consider the installation of well *organized* health departments. In the past, difficulty has been experienced in obtaining men well trained in medicine, epidemiologists, vital statistics, water *supply*, sewage disposal, and in every branch *of city positions*. There are now returning to the civil communities *men* who have served in the Medical Corps of the Army, who are excellently equipped for positions as health officers, laboratorians, vital statisticians, sanitary engineers, industrial hygienists, school medical inspectors, and the like. The American Public Health *Association* has established a health employment bureau at Boston to supply men for such positions. When they *return from service* they will register with the bureau, and when a request for help comes to the bureau, they will be notified and will be sent to the prospective employers. This service is rendered without pay either to the employers or applicants.

Bequests and Donations.—The following bequests and donations have recently been announced:

United Charities of Chicago, $25,000; Country Home for Convalescent Children, $7,000; Children's Memorial Hospital, Visiting Nurse Association, and Grant Hospital, each $5,000; as a nucleus for a fund to be established for a home for crippled soldiers and sailors, $100,000 by the will of Mrs. Augusta Lehmann.

Philadelphia Hospital for Cripples, $10,000, and one half of the principal of the $10,000 trust fund after the death of the niece of testatrix and payment of other bequests: Hahnemann Hospital, Philadelphia, $5,000 by the will of Mrs. Frances W. *Thorpe*.

Jewish Hospital Association, Philadelphia, $1,000 by the will of Walter E. Steppacher.

For the proposed memorial hospital at Albion, Mich., a pledge of $2,500 by Dr. Albert B. Grant, *Albion*.

Johns Hopkins Hospital, $3,500 to be known as *the Dr. John Dixon Fund*, the income to be used in promoting the comfort and welfare of the hospital nurse, and Presbyterian Eye, Ear, Nose and Throat Hospital, Baltimore, $1,500 as a tribute to the memory of Dr. John Dixon, by the will of Mrs. *Ada B. B. Dixon*.

Yale University Medical School, New *Haven, Conn.*, a donation of a fund of $80,000 to be known as the *physiologic* laboratory building fund, to be used ultimately for the construction of a physiologic laboratory and pending this the income to be used for the *benefit* of the department of *physiology* of the Yale University, Department of Medicine, by Mr. and Mrs. Howard H. Spaulding, Jr., Chicago, who gave $50,000; Mr. *Benjamin* H. *Throop*, who gave $25,000, and Mr. J. Ogden Armour, Chicago, who donated $5,000.

Hebrew Maternity Hospital, Montreal, Que., $28,905, *in* the first four days of the campaign for $50,000.

FOREIGN

Hospitable Offer of University of Bordeaux.—The authorities of the University of Bordeaux have announced that American physicians who request it will be admitted to graduate medical courses. Also that a certain number of American students will be admitted to the courses and laboratory privileges of the university. The university also expressed its desire for an interchange of professors.

Health Conditions in Germany.—The Associated Press publishes an interview with Lieut.-Col. Seale Harris, M. R. C., Birmingham, Ala., concerning a recent visit to Germany east *of the* Rhine. It is stated that the German nation is bankrupt and the people starving, the bread and *food* very poor and limited in *quantity*. Colonel Harris reports that tuberculosis is increasing and skin diseases due to lack of nourishment and the lack of soap are prevalent.

Typhus Fever.—A report from Persia states that famine and an epidemic of typhus fever exist at Tabriz, and that Gordon Paddock, American Consul at Tabriz, has appointed a relief committee to take charge of the situation.——An epidemic of typhus fever has broken out in many Russian cities. It is reported that twelve physicians and forty nurses have died in Petrograd, and that the disease is raging in Kiev and Kovel and also is prevalent among the Lithuanian soldiers.

Infant Mortality in Spain.—The *Archives de Médecine des Enfants*, Paris, relates that Dr. M. Vargas, professor of pediatrics and dean at the University of Barcelona, founded in his native town, Barbastro, with 7,000 inhabitants, an infant consultation and dispensary and milk station, or, as he called it, the Instituto Nipiologico. A Child Welfare Week was recently celebrated there, at which it was announced that the infant death rate had been reduced by 50 per cent. during the three years since the institution was founded. Dr. Vargas is director of the Spanish children's journal, the *Medicina de los Niños*, and was the leader of the delegation of Spanish physicians who recently visited France and were invited to lecture at the Faculté de médecine. The topics of the lectures delivered were "Rachitis," "Antityphoid Vaccination," and "Influenza in Spain."

Death of Spanish Physicians Visiting Prison Camps in Germany.—The *Siglo Medico* of January 4 publishes a communication from the government to the effect that according to notices received from the Spanish embassy at Berlin, all of the Spanish physicians who have been visiting the prison camps have been attacked with influenza. The strain of the continuous journeying under unfavorable conditions and the privations in food readily explain the spread of the disease, which is common in the camps, to the visitors. One of the party, Dr. F. Perez Garcia, did not wait for his complete recovery from a light attack of influenza acquired at the Hannover camp, but started out to visit the other camps. He was obliged to return after visiting the camp at Minden where he acquired a pulmonary infection to which he succumbed in six days. The other physician of the party, Dr. Valderrama, of the naval medical corps, also died after arriving in Switzerland, in consequence of influenza acquired in the course of his official trip of inspection.

Brazilian Hospital in France.—The *Paris Médical* relates that Dr. Mourier, the undersecretary of state for the army medical department, recently visited the Brazilian hospital organized in France by Dr. N. de Gouvea, chief of the Brazilian medical mission to France. Dr. Mourier was accompanied by the inspector general, Dr. Février, and the latter presented the cross of the Légion d'honneur to Dr. P. de Rico Branco, an eminent surgeon from Brazil who volunteered in August, 1914, for service in France and has been at work there constantly since. Dr. Mourier in the name of the French government expressed the gratitude of the French to the Brazilian government for its generous initiative and to the members of the mission who came to help the wounded. The mission is said by the *Annaes Paulistas* to consist of fifty physician surgeons, besides a body of students and soldiers to guard the hospital in the field of operations. The mission is under the orders of the chief command of the Brazilian military service. The hospital was to be equipped for 500 beds. There was quite a large party from S. Paulo in the mission, led by Dr. B. Montenegro, recently appointed lieutenant-colonel, and member of the editorial staff of the *Annaes Paulistas de Medicina e Cirurgia.*

CORRECTION

Michigan News.—In The Journal for January 25, it was stated under "Michigan News" that Dr. James W. Inches had been made police surgeon of Detroit. This was an error, as Dr. Inches is now commissioner of police. It was also stated that $5,000 had been requested for a new department of health building. The sum requested was $500,000.

SOUTH AND CENTRAL AMERICA, MEXICO AND WEST INDIES

Deaths in the Profession.—Dr. Ricardo S. Gomez, professor of anatomy at the University of Buenos Aires and chief of the women's department of the Hospital Alvear.——Dr. Elias Toro, professor of external pathology at Caracas and director of the newly founded school of pharmacy.

Reciprocity Between Mexico and Japan.—We understand from the *Revista Medica* of recent date that a treaty has been concluded between Mexico and Japan to the effect that the credentials and titles necessary for the practice of medicine in either country will be accepted in the other. It is stated that this is the only reciprocity treaty in respect to the liberal professions into which Mexico has entered as yet.

Child Welfare Congress Postponed.—The second Congreso Americano del Niño, which was to have been held at Montevideo in December, was postponed till May, 1920, on account of the problems arising from the termination of the world war and the prevailing epidemic of influenza. These rendered it impossible for the government or the profession to give this important international gathering the attention it deserved.

MEXICO LETTER

Mexico City, Feb. 2, 1919.

Echoes of the Typhus Congress

Besides the communications presented to this congress mentioned in my last letter, should be noted one presented by Dr. F. Ocaranza who, aided by Dr. J. J. Izquierdo, has been studying the behavior of the leukocytes in tabardillo, making 162 examinations of blood from nineteen typhus patients. They found constantly a polynuclear leukocytosis with hypolymphocytosis and aneosinophilia. The fever curve parallels the leukocytosis; any divergence between them is a sign of grave prognosis. Dr. Izquierdo has also studied alone the retention and elimination of chlorids in th ecourse of typhus. He reported that the chlorid content of the blood in twelve typhus patients was constantly normal. Hence he condemned the practice of saline infusion in typhus, as liable to expose the patients to the danger of edema. Dr. F. Bulman read a paper on the relations between pregnancy and tabardillo.

Smallpox

This terrible disease which unfortunately never disappears completely from our country, has appeared in the frontier state of Sonora, and in Hermosillo, the capital, there have been a number of cases. It is expected that the disease will not spread, as active measures against it have been undertaken.

Still the Influenza Epidemic

News has been received that epidemic influenza has reached Santa Rosalia in lower California, but the death rate from it has not been high.

The Agricultural College

The School of Agriculture which has been closed for some time is to open anew, Feb. 5, 1919. Its course of studies include veterinary medicine besides the courses of agriculture and agronomic engineering.

Anticruelty to Animals Societies

Societies for this purpose are being founded among the children in the schools in order to train them in consideration for animals.

Baby Show

A local newspaper, in order to stimulate breast nursing as a means to improve the race and dam the flood of infant deaths, has founded a gallery of robust breast fed infants less than 1 year old. The picture of the infants are published.

BUENOS AIRES LETTER

Buenos Aires, Dec. 29, 1918.

Sanitary Inspection Against Influenza

The disappearance of influenza at Buenos Aires and at Montevideo since the third week in November has rendered unnecessary the measures adopted by mutual agreement between the Departamento de Higiene of Argentina and that of Uruguay to check the spread of influenza. December 2, the medical examination that was enforced at the port of Buenos Aires from 7 a. m. to 10 p. m. was suppressed, and December 15 all prophylactic measures were dropped. However, the sanitary inspection was still maintained for travelers to and from the ports of Uruguay and Paraná as epidemics were known to be still prevailing in some of them. As these disappeared, all sanitary inspection was abandoned December 26.

Public Health Service in Catamarca

The recent epidemic of dysentery in the province of Catamarca rendered evident the lack of measures to combat disease in that region. The *Departamento Nacional de Higiene* now has installed a branch station there, and Dr. Otero has been placed in charge.

Dysentery at Humahuaca

When the epidemic of exanthematous typhus died out in the province of Jujuy, it was followed by an epidemic of dysentery. The provincial government has appealed for help to the national public health authorities.

Regional Arsenic Poisoning

Later investigations have rendered it evident that the zone in the province of Cordoba where chronic arsenical poisoning prevails is quite extensive. Clinical cases have been encountered and the presence of arsenic determined in a zone which commences to the south of Bell Ville and extends to north of San Francisco, the waters of the Tercero river being found to contain arsenic. Drs. F. Reichert and R. Wernicke have been studying how to purify these waters, and have succeeded in obtaining the precipitation of nearly all the arsenic and the vanadium by addition of colloidal iron hydroxid. Identical results can be obtained by adding simply salts of iron, as the waters are alkaline. The city of Bell Ville has begun tests of this procedure on a large scale, in order to decide definitely its practical importance.

Reorganization of Public Health System

Many years' experience has amply established the notorious inconveniences resulting from the continual changes in the chief officers of the Departamento de Higiene Nacional and of the Asistencia Publica of the capital. Each new chief usually makes sweeping changes in the personnel, which practice prevents obtaining competent and experienced employees. Most of the appointments are made for political reasons. The present president of the Departamento de Higiene, Dr. Capurro, has announced that he is going to reorganize the service once more. He has declared that he will soon drop eighty supernumerary employees.

University Notes

The regulation providing for an entrance examination for the Facultad de Medicina is now being combated, a petition having been presented to suppress it entirely or at least for this year. The university authorities have refused to make any concessions. The first year students have refused to take any examination in botany, and are clamoring for the suppression of this branch of study.

The Consejo of the Facultad have sent to the federal government, for appointment to the chair of clinical pediatrics, the names of Dr. M. Acuña, first choice; Dr. M. Santos, second choice, and Dr. J. Sixto, third choice. For the chair of gynecology, Dr. J. Molinari, first; Dr. J. Salvador, second, and Dr. C. Piccardo, third choice.

LONDON LETTER

London, Jan. 22, 1919.

Medical Demobilization

The question of medical demobilization has been referred to in previous letters. An elaborate scheme has now been drawn up intended to apply on personal and professional grounds to all medical officers serving temporarily with the forces. As soon as provision has been made for areas in which the medical service has been dangerously depleted, it is proposed that the demobilization of medical officers shall proceed along lines which take into account: (*a*) length of service; (*b*) age; (*c*) special personal hardships in connection with practices, and (*d*) family responsibilities. For this purpose the names of those *over the age* of 30, Nov. 11, 1918 (the date of the armistice), will be classified in the following groups: (1) those who were mobilized at the outbreak of war; (2) those who have served more than three years; (3) those who have served between two and three years; (4) those who have served between one and two years, and (5) those who have served less than one year. Each group will be divided into four subgroups arranged according to age. Priority of demobilization will be determined according to "*points*," thus awarded according to length of service and age:

(*a*) Men mobilized at the outbreak of the war: over 45, 30 points; between 40 and 45, 29 points; between 35 and 40, 28 points; between 30 and 35, 27 points.

(*b*) Men with more than three years' service: over 45, 26 points; between 40 and 45, 25 points; between 35 and 40, 24 points; between 30 and 35, 23 points.

(*c*) Men with *more than* two years' service: over 45, 22 points; between 40 and 45, 21 points; between 35 and 40, 20 points; between 30 and 35, 19 points.

(*d*) Men with *one year's* service: over 45, 18 points; between 40 and 45, 17 points; between 35 and 40, 16 points; between 30 and 35, 15 points.

(*e*) Men with less than one year's service: over 45, 14 points; between 40 and 45, 13 points; between 35 and 40, 12 points; between 30 and 35, 11 points.

Points will be thus added or subtracted in respect of the modifying conditions named:

1. If in whole-time salaried post, subtract 6 points.
2. If with no paid appointment or national health insurance work, add 3 points.
3. If in single-handed practice, add 3 points.
4. If all members of partnership are on service, and no member of the partnership is otherwise entitled to more than 30 points, add in case of one partner 4 points.
5. If married, add 4 points.
6. If with children or other dependents add 1 point for each dependent (excluding wife) up to a maximum of 4 points.

Additional points may be awarded in respect of financial or other circumstances of an exceptional character which justify a claim to a higher order of priority than that determined by the foregoing provisions. The order of priority of men under 30 will be according to age, the older before the younger.

Medical Members in the New Parliament

The result of the general election as regards the medical candidates is not very satisfactory. Members of the profession were candidates in thirty-two constituencies, but only nine were returned. This, however, is an increase on the number (five) in the last parliament. Among the successful candidates are Dr. Christopher Addison (minister of reconstruction in the last parliament) and Sir Auckland Geddes (minister of national service), whose careers were described in The Journal, Dec. 21, 1918, p. 2090; Sir Watson Cheyne and Sir William Whitla (professor of materia medica, Belfast University), and Sir Robert Woods (professor of laryngology and otology, Trinity College, Dublin). Excepting Sir Auckland Geddes and Dr. Addison, all these eminent members of the profession were returned for university seats. One leading man, Sir Wilmot Herringham, physician to St. Bartholomew's Hospital and major-general in the Army Medical Service, was a defeated candidate for the London University. In Ireland three physicians were returned, in all cases Sinn Feiners (Republicans). All the medical candidates came forward on general political grounds; and only in the cases of the universities, in which there is a considerable medical vote, do they represent medical opinion in any special sense.

The Harvard Unit in London

The executive committee of the interallied fellowship of medicine (described in these columns, January 25) entertained at dinner the members of the Harvard Surgical Unit, which is paying a short visit to London on its way home from France. Sir William Osler, chairman of the executive committee, presided. The toast of the Harvard Unit was proposed by Dr. Norman Moore, president of the Royal College of Physicians. Lieut.-Col. Hugh Cabot, in responding, said that the unit was the outcome of a grave decision and one that gave general satisfaction at a time when there was an endeavor to maintain the neutrality of the United States. Throughout the first year or more of the life of the unit it was a succession of changes. The original conception was that it should be started by Harvard and followed in succession by other universities. It was not until December, 1916, that the corporation of the university undertook the enlistment of officers for the duration of the war, and that the unit came to stand on a firm foundation. It was only since he had been closely associated with Englishmen, Irishmen, Scotsmen and Australians that he had come really to know that we were, in fact, all of the same blood. Superficial differences tended to hold them apart, unless they realized that these difficulties were superficial. These superficial differences were largely mannerisms and methods of expression. He had been impressed by the fact that when Americans and British worked together they came to admire and understand each other's qualities. He felt very strongly that they must continue not simply to associate together but to bring these peoples together until they had finally locked them in a union which, as he believed, could alone be expected to maintain the peace of the world. He could not follow the eminent thinkers who believed in the League of Nations. The only league of nations in which he could really believe was a true union and understanding between all the branches of the Anglo-Saxon people. He was satisfied that that would be a basis on which might be constructed a league of nations that would do something to maintain the peace of the world.

Lieut.-Col. E. F. Harrison, C.M.G.

Lieut.-Col. E. F. Harrison, to whose investigations the success of the British defense against the poisonous gases of the Germans was mainly due, has died from influenza at the age of 49. His premature end was largely due to being worn out by his labors. Before the war he was one of the leading scientific pharmacists in England. He was a member of the board of examiners of the Pharmaceutical Society and for a time head of the analytic department of Burroughs Wellcome & Co. He performed for the *British Medical Journal* a series of analyses of proprietary articles which were published under the title "Secret Remedies," a book which created a considerable sensation and produced much resentment among nostrum proprietors. Soon after the Germans made their first gas attack he joined the Sportsmen's Battalion of the British Army. He was moved to enlist at what was an advanced age for such a purpose by the detestation he felt for the prostitution of chemical science by the enemy in the use of poison gas. He felt that the Allies must reply in kind and that his vast chemical knowledge should be placed at the service of the War Office. After his period of training he transferred to the Royal Engineers in a response to a call for chemists, and soon afterward was made a lieutenant. He worked first at the Royal Army Medical College, where the problem of protecting our troops against gas was being attacked. He labored strenuously in providing a protection, not against one gas but against a large number, as he recognized that this fiendish method of warfare had great possibilities. The tests involved the wearing of the protective device in an atmosphere of gas as long as he could stand it, and his health suffered in the continual exposures. But he was undeterred, and up to the end of his career was eager to try on himself any new apparatus or the effect of a new gas when wearing a protector. He devised the first box respirator that was supplied to the troops. The mode of protection involved first the working out of a method—for making permanganate granules. Then it was necessary to discover the best method of preparing charcoal, the absorptive powers of which may vary twenty-fold, according to the method of preparation. These substances were at first made by private firms, but their resources not proving adequate for the enormous demands, he organized large factories where the process of manufacture was carried out under his direction. The magnitude of his task will be realized from the fact that in addition to 15,000 work people employed in the antigas department, 120,000 were engaged in the manufacture of box respirators. The factories supplied nearly 50 millions of respirators. His organization was so good that he never failed to respond when there was an increased demand, however sudden and unexpected. When the Americans failed to turn out as they expected a sufficient number of respirators in time for their troops, he was able to supply all deficiencies. For the excellence of his work he was promoted to Major in April, 1916, and Lieutenant-Colonel in January, 1917. A short time before he died he was appointed controller of the Chemical Warfare Department.

Another analytic chemist, Capt. Alexander Gemmell, who worked under Lieutenant-Colonel Harrison, has also died. His end is also attributed to experiments to insure protection of our troops against poison gas.

THE PROJECTED MINISTRY OF HEALTH IN GREAT BRITAIN

(*Special correspondence*)

London, Feb. 1, 1919.

American physicians will follow with unusual interest the agitation that has been aroused in England in relation to the possible establishment of a ministry of health. Many of the questions that have been raised for debate or consideration are identical with the issues involved in the creation of a comparable office in our own government, so that the public interest of medicine and hygiene might be represented by a responsible member of the cabinet. There can be no doubt that all thinking persons are having their attention turned to the important subject of the health of the nation. The war has taught the lessons of having a citizenship that is "fit" for the work of the world at all times. Enthusiastic groups of both the medical profession and the laity are interested in all sorts of ways—practical, philanthropic, scientific, sociological—in a considerable diversity of matters that are in essence a part of the health scheme. The daily press is an index of part of the agitation and performance in respect to such subjects as child welfare, maternal care, the campaign against venereal disease, industrial hygiene, tuberculosis and various epidemic diseases that form local or even national menaces. Naturally it has seemed timely to ascertain whether some correlation of effort is not advisable. Two generations ago the primary impulse to accomplish something for people's well-being was one of charity. Today a more pragmatic aim underlies much of the interest in health conservation; it is a motive of concern for national vitality, for the elimination of disease because it pays in the long run; it is the desire to deal with disease as a state or a nation, since the objections to interference with the liberty of the individual have long since been overruled by the advantage of the common good.

Is it possible to frame "a comprehensive scheme big enough for a big ideal"? Dr. Addison, the new president of the Local Government Board in England who may have charge of the proposed bill for establishing a ministry of health, believes that it will be quite possible "to improve the national armor against disease" by the projected consolidation of efforts under the financial assistance of the state. Among others who are enthusiastic for the new movement, Addison has pointed out that the business of the health ministry does not begin and end with hospital matters. In addition to regular clinics in the larger centers of population it is proposed to organize portable clinics and laboratories. The training and organization of midwives and nurses must be undertaken in a systematic way. The problems of maternity will demand scientific attention. All branches of sanitation and preventive medicine will be pursued. In a broad sense the organization will be that of a medical intelligence department quite as much as that of an administration bureau. There will be laboratories and other features necessary for research; and information of diverse character will be gathered by the public medical authorities.

There has been considerable speculation as to a possible antagonistic attitude on the part of the medical profession on the score that all physicians would presently either become public servants or be without work. According to Dr. Addison, no such socialization of medicine is contemplated; in fact, it seems to be recognized that the function of the new movement is to supplement, not to supplant, the work of the practitioner, whose position will in no way be interfered with. To endeavor to keep as many people as possible as well as possible, and to insure that no sick person shall lack adequate care and attendance, may necessitate new posts and create a demand for many physicians; but any work in the direction of diagnosis and therapy must be conducted under such auspices as will carry professional opinion with it. The quack and charlatan may lament, but the honest medical man need not bewail the expansion of knowledge and opportunity.

Some concern has also been expressed regarding the fate of existing hospitals established as private benefactions. Reforms may, of course, be initiated at the suggestion of a central authority on health matters. It would assuredly not be difficult to enumerate instances in which such interference might be a blessing in disguise. But we cannot imagine that any present-day practicable schemes would even dream of supplanting existing organization. The hospitals and other institutions that have heretofore been maintained by voluntary contributions need neither be abolished nor turned into state establishments. They should be assisted in return for services that they may be invited to render.

Some alarm has been expressed in England regarding the "danger of medical despotism" in any compulsory scheme dealing with prenatal care and the welfare of children. A woman publicist has even designated a ministry of health with legalized authority over such matters as a menace to women and children. The recent restrictions of personal liberty, as exhibited in the outcome of the prohibition movement in America, must teach, however, that the principle of the greatest common good is likely to limit our individual freedom in many ways in the future as it has done in the past. Democracy does not mean license to behave without regard to the welfare of others.

A further, perhaps more debatable, concern has been expressed with regard to established governmental research bureaus in medicine under the new English scheme. There is no question that a ministry of health should have a department for scientific investigation, which is the very backbone of progress. But there is a medical research committee already in existence as a permanent institution created under the English national insurance act. To some it has seemed advisable that this should continue in an independent existence because medical research in the broader sense must have a wider sphere than that of national or insular concern. As one writer has remarked, medical research must deal not with England and Wales, but with the empire. There is much to be said in favor of some individuality and independence of effort in research, even at the expense of some duplication.

PARIS LETTER

PARIS, Jan. 16, 1919.

Enrolling for Military Service the Young Men of the Invaded Zone

It has been decided by the premier not to delay enrolling the young men of the classes of 1915 to 1919 (from 19 to 23 years of age) not yet registered, and to summon for reexamination the classes of 1913 to 1915, who have been held in the invaded regions which have just been reconquered. A special commission will classify these young men according to their fitness for service. The young men who are accepted for the army or the auxiliary service will be assigned, with as little delay as possible, to the corps which they would have joined if they had been called to the colors at the same time as their comrades. The others will be left in civilian life either permanently or subject to another examination after a specified interval.

Physicians and the Tax on War Profits

Deputy M. Bergeon made inquiry of the minister of finance as to the following: (1) Supposing that the law of July 1, 1916, concerning the contribution of war profits, were applied to physicians, would the commissions charged with the administration of that law have the right to demand of physicians that they furnish a list of their patients, and, if so, (2) would the physicians who complied with that demand be considered as having violated professional confidence or of having committed an offense rendering them liable to punishment by law? To these questions the minister replied that physicians, in common with all other contributors, should furnish the commission with all the data needed to establish the basis of taxation. If a list of patients must be supplied in order to arrive at the necessary conclusions, it will not be considered as encroaching on their responsibility inasmuch as they will be conforming to a legal requirement, and, the agents of the law, to whom this information will be given, are themselves bound to professional secrecy.

The Activities of the American Red Cross

MERCHANDISE STORAGE

In order to increase its efficiency, the American Red Cross divided France into zones when it first began its work. These zones have been abolished, and warehouses have been established in the devastated regions in which the needed merchandise will be stored by the Comités de secours appointed by the French government as it is received from the American Red Cross. At the cessation of hostilities, considerable material and merchandise were left in the hands of the Red Cross. Hence the Red Cross authorities have asked the French government to cooperate in the distribution of these stores among the destitute population. Warehouses have been or will be established at Lille, Amiens, Laon, Châlons, Mézières, Verdun, and in Belgium at Brussels, Courtrai and Adinkerke.

TUBERCULOSIS PROPAGANDA

The director of the American Antituberculosis Mission recently called a meeting in Paris of the representatives of this propaganda, who, during the past five months, have been making known all over France the most practical methods and the most simple means for combating and checking tuberculosis. Professor Gunn, assistant director of the Mission, reported the good results that have been obtained and detailed the program to be followed for 1919.

BALKAN RELIEF

The American Red Cross also sent a commission to the Balkans for the purpose of giving relief in Greece, Roumania, Serbia and Montenegro. The first contingent, in charge of Col. Henry W. Anderson, American Red Cross commissioner for the Balkans, has already left Paris; the remainder of the personnel will leave early next week. A special group consisting of physicians, nurses, etc., will be sent into each one of the four countries named, and all will be in charge of a directing staff whose headquarters will be at Belgrade. A special commission has been working in Serbia. It has furnished food and clothing to thousands of refugees in southern Serbia. This same commission will give relief to the people of northern Serbia and of eastern Macedonia.

Nurse Receives Decoration of Legion of Honor

Mme. Veuve Marie Segui, temporary nurse in military hospitals, has been made a chevalier of the Legion of Honor, with the following citation: "Devoted nurse, lavishing care on the war wounded since Sept. 1, 1914, was wounded while dressing a patient suffering from a grave septicemia and consequently contracted an infection which endangered her life and necessitated the amputation of her left arm."

Deaths

Dr. Louis-Edouard Bureau, doctor of natural science and formerly professor of botany at the Muséum d'Histoire naturelle, aged 88. He had been a member of the Académie de médecine, section of therapeutics and medical natural history, since 1901.——Dr. Frezoul, a former senator, aged 82 years, at Foix, département de l'Ariège. He served as a volunteer member of the medical corps during the Franco-Prussian war of 1870.

Dr. Etienne Destot, médecin-major of the first class, medicolegal expert of the tribunal de la Seine, died suddenly, aged 54 years. For several years he had been specializing in medical electricity and roentgenology. He published a number of works, notably on physiologic disturbances and the atrophy caused by the roentgen ray. When mobilization was begun he was put in charge of a hospital installed in a gymnasium in Paris.

Dispensary for Refugees

The Bureau des Secours généraux américains has opened a dispensary and a small hospital for refugees and évacués at Angoulême, département de la Charente. This work will be in charge of Dr. Lillie A. Arnett, of the Children's Bureau, who also has charge of the colony for children at Saint-Même, and visits regularly several small communes in the département de la Charente. The American Red Cross recently opened a dispensary for children at Essones in the département de Seine-et-Oise.

Books for the Blind

The Conférence of the "Livre de l'aveugle" was held in Paris under the presidency of M. Charles Krug, president of the Conférence des oeuvres d'assistance aux aveugles de guerre. Three sections were established: One section, presided over by General Balfourier, president of the Association Haüy pour le bien des aveugles, is charged with the task of cataloging and establishing a bibliographic service for books printed in Braille type; the second section, presided over by M. René Vallery-Radot, president of the Amis des soldats aveugles, will have charge of the printers and copyists and will ascertain the needs of blind readers; the third section, presided over by M. Ernest Vaughan, director of the Hospice des Quinze-Vingts, will have charge of the establishment of libraries for the blind.

Decoration of Legion of Honor for Brazilian Physician

At the time of his visit to the hospital maintained by the Brazilian government, Dr. Louis Mourier, undersecretary of state for the Service de Santé militaire, conferred the cross of the Legion of Honor on Dr. Paul de Rio Branco, surgeon of the hospital, who voluntarily gave his services to France about Aug. 29, 1914, and has been working in behalf of the wounded continuously ever since.

Sir Almroth Wright

The Académie des Sciences has elected Sir Almroth Wright, of London, corresponding member for the section on medicine.

Recrudescence of Rabies

Rabies, which had disappeared almost entirely before the war, has, since the beginning of hostilities, made alarming progress. This is attributed wholly to the many dogs wandering around in the invaded districts; but the ineffectiveness of the police measures is also a factor. Before the war between 300 and 400 persons presented themselves annually at the Institut Pasteur for antirabies treatment; in 1916, 1,388 patients were treated; 1,543 in 1917, and 1,800 in 1918.

Marriages

HUGO SELWYN TAIT, Asst. Surg., Lieut. (j. g.), U. S. Navy, to Miss Barbara Smith, at New Orleans, November 30.

SIDNEY CLEVELAND NILES to Miss Eva Brandenburg, both of Toledo, Ohio, at Washington, D. C., January 15.

GUSTAVE GOODMAN HERPE to Miss Elsa Kuhn, both of Chicago, February 11.

Deaths

Clarence John Blake ⊕ Boston; Harvard Medical School, 1865; University of Vienna, Austria, 1866; aged 75; a member of the American Academy of Ophthalmology and Oto-Laryngology; American Laryngological, Rhinological and Otological Society, and American Otological Society, and president of the latter organization in 1876-1877; president of the Ninth International Otological Congress; once president of the Boston Society for Medical Improvement and the Boston Society for the Advancement of Physical Education; lecturer on otology in his alma mater from 1870 to 1875; instructor from 1875 to 1888, and professor from 1888 to 1913, and later professor emeritus; aural surgeon to the Massachusetts Charitable Eye and Ear Infirmary since 1871; president of the Infants' Hospital, and manager of the Children's Hospital, Boston; editor of the *American Journal of Otology* from 1879 to 1892; author of a standard textbook on operative otology; died at his home, January 29.

Samuel Light Hauck ⊕ Ottumwa, Iowa; Rush Medical College, 1891; aged 49; for twenty-seven years surgeon in the voluntary relief department of the Burlington System, but for the last few months identified with the sanitary department of the Illinois Central Railroad in Chicago; chief surgeon of the American Commercial Travelers' Association; died at his home, in Ottumwa, January 22, from cerebral hemorrhage.

Henry Mitchell ⊕ Asbury Park, N. J., and Daytona Beach, Fla.; Bellevue Hospital Medical College, 1867; aged 73; president of the board of health of Asbury Park from 1880 to 1894; member, secretary and executive officer of the New Jersey State Board of Health from 1894 to 1908; formerly surgeon of the One Hundred and Third Infantry, N. Y., N. G.; died at his winter home at Daytona Beach, Fla., January 31.

Ashley Wilson Fly ⊕ Galveston, Texas; Louisville (Ky.) Medical College, 1875; aged 63; a specialist in surgery; mayor of Galveston from 1893 to 1899; for several terms president of the board of health, and chairman of the committee on public health; professor of anatomy in the Texas Medical College; for two terms a regent of the University of Texas; died at his home, January 24.

Heikobus Johannes Hubertus Hoeve, Meherrin, Va.; University of Illinois, Chicago, 1905; aged 37; at one time a member of the Iowa State Medical Society, and professor of anatomy, and director of the pathologic department in Drake University, Des Moines; a member of the American Association of Anatomists; died at his home, December 22, from pneumonia following influenza.

Thomas Hundley Seay ⊕ **Capt., M. C., U. S. Army,** Laurel, Miss.; University of Nashville, Tenn., 1906; aged 36; head of the Laurel General Hospital, and a member of the state board of health; who had been on duty at Fort Oglethorpe, Ga., until his discharge from the service a short time ago; died at his home, January 15, from pneumonia following influenza.

Leroy Grant Armstrong, Boscobel, Wis.; Rush Medical College, 1859; aged 84; a member and once president of the State Medical Society of Wisconsin; surgeon of the Sixth, Eighth and Forty-Eighth Wisconsin Volunteer Infantry (Iron Brigade) during the Civil War; for nearly fifty years clerk of the local board of education; died at his home, February 1.

Edward Lewis Rochfort ⊕ **Lieut., M. C., U. S. Army,** New York City; Yale University, New Haven, Conn., 1912; aged 28; an instructor in United States Government Neurological School No. 1, New York City; who received his discharge from the Army in December; died at the Neurological Institute, New York City, January 26, from influenza.

Ralph Edwin Shrom ⊕ **Asst. Surg., Lieut. (j. g.), U. S. N. R. F.,** Philadelphia; Jefferson Medical College, 1904; aged 36; a specialist in gynecology; assistant surgeon to the Philadelphia Polyclinic and Strittmatter's Private Hospital, Philadelphia; died at his home, January 26, from pneumonia following influenza.

Walter Greenough Chase ⊕ Boston; Harvard Medical School, 1901; aged 59; secretary of the pathologic section of the Pan-American Medical Congress, at its meeting in Panama in 1905; skilled in photography and the roentgen ray; a specialist in the treatment of nervous diseases; died at his home, January 27.

Zack Jackson Moore ⊕ **Lieut., M. C., U. S. Army,** San Antonio, Texas; University of Texas, Galveston, 1915; aged 32; who entered the service in July, 1917, and was on duty with the British Expeditionary Forces in France and was wounded on March 24; died in Woolwich, England, October 26, from pneumonia.

George Newton Ferris, Brooklyn; Long Island College Hospital, Brooklyn, 1879; aged 64; a member of the Medical Society of the State of New York; from 1881 to 1889 superintendent of the Kings County Insane Asylum; died suddenly at the home of his sister in Brooklyn, January 28, from heart disease.

Rienzi Robinson ⊕ Danielson, Conn.; Long Island College Hospital, Brooklyn, 1869; aged 76; formerly president of the Connecticut State Medical Society; a member of the consulting staff of the Day-Kimball Hospital, Putnam, Conn.; died at his home, January 31, from pulmonary tuberculosis.

Valentine Milton Reichard ⊕ Fairplay, Md.; Jefferson Medical College, 1882; aged 60; one of the most highly regarded physicians of western Maryland; one of the founders of the Washington County (Md.) Medical Society; died at his home, January 26, from heart disease.

John Dwight Freeman ⊕ Topeka, Kan.; Rush Medical College, 1897; a chief surgeon of the Atchison, Topeka and Santa Fe Railway Hospital, Topeka, since 1899; died in Stormont Hospital, Topeka, January 26, from pneumonia following influenza.

Edward Sanders, New York City; New York University, New York City, 1876; attending physician to Mount Sinai Hospital and Dispensary and physician to the Hebrew Orphan Asylum; died at his home, January 29, from heart disease.

Charles Seymour Hart, Marietta, Ohio; Columbus (Ohio) Medical College, 1877; aged 62; a member of the Ohio State Medical Association; for several years surgeon for the local street railway company; died at his home, January 25.

W. Rice Holtzman, Stinesville, Ind.; Louisville (Ky.) Medical College, 1893; aged 51; a member of the Indiana State Medical Association; for two terms postmaster of Stinesville; died at his home, recently, as the result of influenza.

Francis Webb Drew, St. Louis; College of Physicians and Surgeons, Keokuk, Iowa, 1886; aged 67; at one time a member of the Missouri State Medical Association; died at his home, January 25, from cerebral hemorrhage.

James Andrew McQuillan ⊕ **Lieut., M. C., U. S. Army,** Jackson, Mich.; St. Louis University, 1912; aged 30; on duty with the American Expeditionary Forces in France; was killed by a shell near Valenciennes, October 23.

Henry Blender ⊕ **Lieut., M. C., U. S. Army,** Okeene, Okla.; Keokuk (Iowa) Medical College, 1907; aged 34; stationed at Camp Greenleaf, Ga.; died at that place, October 7, from lobar pneumonia following influenza.

Robert Valentine Sawin, Brimfield, Mass.; Jefferson Medical College, 1885; aged 62; a member of the Massachusetts Medical Society; died at the home of his daughter in Storrs, Conn., January 19, from nephritis.

Maurice Steinberger ⊕ Bridgeport, Conn.; University of Budapest, Hungary, 1889; Eclectic Medical College of the City of New York, 1909; aged 53; died at his home, December 23, from lymphatic leukemia.

Henry A. Wall ⊕ Tacoma, Wash.; University of Oregon, Portland, 1889; aged 53; formerly city health officer of Tacoma; died in St. Joseph's Hospital in that city, January 24, from hemorrhage of the stomach.

Andrew Lee Wagoner, Hobart, Okla.; Vanderbilt University, Nashville, Tenn., 1894; aged 52; a member of the Oklahoma State Medical Association; died at his home, December 26, from cerebral hemorrhage.

William J. Armstrong, Washington, D. C.; Georgetown University, Washington, 1870; aged 83; a member of the Medical Society of the District of Columbia; died in Washington, D. C., December 28.

A. A. Hyer, Washington Court House, Ohio; American Eclectic Medical College, Cincinnati, 1882; aged 71; at one time a member of the Ohio State Medical Association; died at his home, January 28.

J. M. W. Langsdale, Florence, Ind.; Medical College of Ohio, Cincinnati, 1874; aged 71; for forty-two years a practitioner and druggist of Florence; died at his home, January 28, from heart disease.

Harris Soper Greeno, Fairhope, Ala.; Bellevue Hospital Medical College, 1882; aged 87; first mayor of the Fairhope single tax colony; died in Mobile, Ala, February 1.

⊕ Indicates "Fellow" of the American Medical Association.

Joseph H. Haydon ⊕ Newark, N.J.; New York University, New York City, 1872; aged 67; consulting physician to St. James Hospital, Newark; died at his home, January 24, from cerebral hemorrhage.

Hugh L. Routh, Batavia, Ark.; Vanderbilt University, Nashville, Tenn., 1885; aged 74; a member of the Arkansas Medical Society; a veteran of the Civil War; died in Otsego, Mich., recently.

Charles Reinhold Baker, San Francisco; Cooper Medical College, San Francisco, 1900; aged 42; died in Franklin Hospital, San Francisco, January 30, from pneumonia following influenza.

Francis Joseph Ennis, Burlington, Vt.; University of Vermont, Burlington, 1914; aged 31; a member of the Vermont State Medical Society; died at his home, October 27, from influenza.

Albert A. G. Starck ⊕ Philadelphia; Jefferson Medical College, 1883; aged 66; also a graduate of the Philadelphia College of Pharmacy; died at his home, January 30, from heart disease.

William Makepiece Roads, Los Angeles; Medical College of Ohio, Cincinnati, 1887; aged 57; for many years a practitioner of Cincinnati; died at his home, January 10.

Charles Petite Tobin, Hampton, Ark.; Tulane University, New Orleans, 1879; aged 64; died at the home of his sister in Little Rock, Ark., January 14, from pneumonia.

William Mainland Brown, Oakland, Calif.; University of Louisville, Ky., 1872; aged 78; for many years a surgeon on Pacific steamships; died at his home, January 21.

David Harrison Conley, Naples, N. Y.; Cleveland University of Medicine and Surgery, 1868; aged 74; died in Clifton Springs, N. Y., November 8, from nephritis.

Henry Griswold ⊕ New York City; University of Louisvill, Ky., 1864; aged 75; a fellow of the New York Academy of Medicine; died at his home, February 1.

Camillo Bizzozero, Torrington, Conn.; University of Milan, Italy; aged 60; was run over and killed by a train at a grade crossing at Newfield, Conn., December 26.

Amant H. Ohmann-Dumesnil, St. Louis; Washington University, St. Louis, 1880; aged 61; died in the City Hospital, St. Louis, January 18, from tuberculosis.

Orlando Ewers, Nunn, Colo.; formerly of DeSoto, Wis.; aged 72; a practitioner for forty-four years; died at his home, December 25, from cerebral hemorrhage.

John Harford Chatten, Cincinnati; Eclectic Medical Institute, Cincinnati, 1859; aged 79; died suddenly in Akron, Ohio, January 20, from cerebral hemorrhage.

Joseph Allard, Fall River, Mass.; Indiana Eclectic Medical College, Indianapolis, 1887; aged 62; died at his home, December 15, from lobar pneumonia.

A. L. Nance, Gainesville, Ga.; Philadelphia University of Medicine and Surgery, Eclectic, 1868; aged 74; died at his home in October, 1918, from ascites.

James Patterson Burd, Philadelphia; University of Pennsylvania, Philadelphia, 1871; formerly of Juniata County, Pa.; died in Philadelphia, Dec. 16, 1918.

William I. Ballinger, Plain City, Ohio; Western Reserve University, Cleveland, 1866; aged 90; died at his home, December 29, from senile debility.

Henry L. Bawden, Ismay, Mont., formerly of Davenport, Iowa; State University of Iowa, Iowa City, 1873; aged 73; died at his home, January 22.

John Noble Yates, Wilmington, Del.; Hahnemann Medical College, Chicago, 1895; aged 74; died at his home, January 17, from cerebral hemorrhage.

Charles Hatfield Greenough, Bayport, N. Y.; Bellevue Hospital Medical College, 1873; aged 69; died at his home, January 17, from septicemia.

Robert Stewart, St. Joseph, Mo.; Missouri Medical College, St. Louis, 1856; aged 83; died at his home, January 14, from cerebral hemorrhage.

Jacob Leonard Eisendrath ⊕ Chicago; University of Illinois, Chicago, 1904; aged 38; died at his home, January 25, from pneumonia.

Thomas Lewis Riley, New York City; Bellevue Hospital Medical College, 1897; aged 47; died in Bellevue Hospital, January 24.

John A. Kressley, New Tripoli, Pa.; Hahnemann Medical College, Philadelphia, 1889; aged 56; died at his home, January 19, from rheumatism.

The Propaganda for Reform

In This Department Appear Reports of the Council on Pharmacy and Chemistry and of the Association Laboratory, Together with Other Matter Tending to Aid Intelligent Prescribing and to Oppose Medical Fraud on the Public and on the Profession

CERELENE NOT ADMITTED TO N. N. R.

Report of the Council on Pharmacy and Chemistry

The Council has authorized publication of the following report declaring Cerelene inadmissible to New and Nonofficial Remedies. W. A. Puckner, Secretary.

Cerelene, a paraffin preparation for the treatment of burns, was submitted to the Council by the Holliday Laboratories, with the statement that it was composed of 84 per cent. paraffin, 15 per cent. myricyl palmitate, and 1 per cent. purified elemi gum to which is added oil of eucalyptus 2 per cent. and betanaphthol 0.25 per cent. It was explained:

> "Myricyl Palmitate is a purified form of Beeswax, free from all impurities, acids, etc., which is solely manufactured by this Company. . . ."

It was also stated that on "special order" Cerelene has been made containing oil of eucalyptus and resorcin, oil of eucalyptus and picric acid, and picric acid alone. The following report on the preparation was presented to the Council by the referee to whom Cerelene had been assigned:

> Cerelene is another compound wax for the treatment of burns. According to the work of Sollmann (J. A. M. A., 1917, 68, p. 1799) it is highly improbable that compound mixtures have any advantage over simple paraffin of low melting point. Cerelene must therefore be considered as an unessential modification of paraffin, and as in conflict with Rule 10; unless definite evidence of superiority is submitted. Cerelene mixtures containing medicinal ingredients also appear unscientific since the evidence that the ingredients do not leave the wax has not been successfully contradicted. Finally, the claims made for Cerelene are rather extreme, and would need some revision before they could be accepted.
>
> The A. M. A. Chemical Laboratory reports:
>
>> The physical properties of Cerelene are as follows:
>>
>> | | |
>> |---|---|
>> | Melting point 50.0 C. by U. S. P. method. | |
>> | Ductility limit...................... | 30.5 C. |
>> | Plasticity limit...................... | 26.4 C. |
>> | Not strong at...................... | 38 C. |
>>
>> Adheres moderately well; detaches with "pulling." On heating, readily loses eucalyptol, and a small amount of resinous substance forms in the bottom of the beaker. If Cerelene is heated to 145 C. and cooled, the resulting product no longer has the properties of the original Cerelene.
>
> It is recommended that the preceding report be sent to the Holliday Laboratories, and that unless its superiority over simple paraffins is demonstrated and the unwarranted claims abandoned, Cerelene be declared inadmissible to New and Nonofficial Remedies for conflict with Rules 6 and 10.

This report was submitted to the Holliday Laboratories with the information that it had been adopted, Oct. 3, 1917. It was also explained that before Cerelene could be accepted, the unofficial and unstandardized constituent "myricyl palmitate" would have to be considered and accepted for New and Nonofficial Remedies since, for obvious reasons, the Council does not accept a preparation which contains an unofficial and unstandardized substance not in N. N. R.

The Holliday Laboratories acknowledged receipt of the Council's report and asked that the matter be held in abeyance until the requested evidence had been obtained. Later the Council was advised that the advertising circulars for Cerelene had been withdrawn with the exception of one giving directions for its use. Five months later, the firm stated that experiments were being made "to determine the actual strength of Cerelene in comparison with other paraffin waxes.

. . ." Nothing further has been heard from the Holliday Laboratories and no reply has been received to an inquiry made Oct. 12, 1918. The Council therefore authorizes publication of its report declaring Cerelene inadmissible to New and Nonofficial Remedies.

Correspondence

"THE LOS ANGELES COUNTY HOSPITAL AND INTERNS"

To the Editor:—Relative to the editorial comment in The Journal, Jan. 4, 1919, p. 46, I believe that the presentation of the facts regarding the Los Angeles County Hospital is so worded as to give a wrong impression of the conditions that exist in this institution. The civil service examinations for interns for the Los Angeles County Hospital are held in San Francisco, Los Angeles, St. Louis, Chicago, and one or two other cities. According to the ranks of the men who take the examinations, the civil service compiles a list. When vacancies occur, the next highest man is called on to see whether he will accept the position.

When osteopaths have been admitted as interns, it simply means that these men took the civil service examinations, and that in due time when vacancies occurred, their names were reached and the positions had to be offered to them. This is due to the fact that a goodly number of the men who take the examinations, and who are high up on the list, do not accept the positions in the first place, or if we wait, then they accept other work. In that way the bunch of eligibles among well trained men reaches an end, and then the only others on the list are those of lesser education and training, who, however, having taken the examinations, are, according to law, to have the privilege of accepting these positions.

There is no thought on the part of the Los Angeles County Hospital authorities to put osteopath interns in that institution. The hospital must, however, have interns, and all it can do is to provide for examinations on a large scale and then hope that well trained men in regular medicine will be in sufficient number on these lists to keep the internships always among that group. In practice, however, it has not worked out that way for the reasons already noted.

George H. Kress, M.D., Los Angeles.

"THE SUPPLY OF PRACTICAL NURSES"

To the Editor:—I read with much interest your excellent editorial, "The Supply of Practical Nurses," which appeared in The Journal, January 25. Congratulations! I was glad to hear some one with backbone speak up. Truer words were never spoken. The nursing situation here in Portland and in Maine, for that matter, has been, and is, most trying, for just the very reasons mentioned in your editorial.

Adam P. Leighton, Jr., M.D., Portland, Maine.

HARMLESSNESS OF GLASS IN DIGESTIVE TRACT

To the Editor:—The authors of the recent excellent experimental proof of the harmlessness of glass in the digestive tract (The Journal, Dec. 28, 1918, p. 2127), and that part of the public which has been so greatly worked up over rumors of contamination of food by glass, may be equally interested to recall that this subject was one of practical interest long ago, when murder by poison was not infrequent.

When Benvenuto Cellini was a prisoner of the pope in Rome in 1539, an enemy in the papal court attempted his life by the use of diamond dust in the prisoner's food. As Cellini says:

> In itself it is not poisonous at all; but being extraordinarily hard, its sharply pointed angles do not become rounded when it is reduced to powder, as would be the case with other stones. Only the diamond keeps its sharp edge, so that, if it enters the stomach along with food, during the process of digestion it sticks to the coats of the stomach and the bowels, and as the new food comes ever pushing forward, it is not long before it pierces them and death is the result; whereas no other kind of stone or glass sticks to the organs, but goes on its way with the food.—Life of Benvenuto Cellini, translated by McDonnell, Everyman's Edition, p. 263.

Fortunately for Cellini, the jeweler employed to powder the diamond pocketed the gem and substituted a softer stone, a beryl, which caused no harm at all.

George W. Corner, M.D., Berkeley, Calif.

"METHEMOGLOBINEMIA DUE TO POISONING BY SHOE DYE"

To the Editor:—I am glad that Dr. Stifel has so forcibly presented the findings of the cases of nitrobenzene poisoning from shoe dye (The Journal, Feb. 8, 1919, p. 395). It has long been the custom for shoe dressing manufacturers to add a certain amount of this very dangerous substance to their wares. I am unable to find that it serves any other purpose than the odor it gives the preparation. It would seem desirable that some one should vigorously protest against the reckless use of this particular poison. Having myself seen fatal cases from nitrobenzene poisoning, I am strongly prejudicial against the continued use of this substance as a scent for shoe dressings, soaps and the so-called disinfectants, simply because it is a cheap perfume and covers the unpleasant odors. The medical profession should take a definite stand against useless poisons.

W. S. Wadsworth, M.D., Philadelphia.

SUBNORMAL TEMPERATURE FOLLOWING INFLUENZA

To the Editor:—During this pandemic of influenza I have observed many patients with a temperature of 94, and several much lower than 94. Some few I find with a decided slowness in the heart's action. Is this low temperature due to a relaxed condition of the entire nervous system and lowered vitality brought about by improper nourishment? In my experience I find that patients having the influenza or those recovering from it are usually suffering with anorexia. This, I understand, would lower the vitality; but I cannot see why the unusual subnormal temperature is so marked.

J. P. Brandon, M.D., Essex, Mo.

Queries and Minor Notes

Anonymous Communications and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted, on request.

OFFICER'S RIGHT TO A MONTH'S PAY WHEN DISCHARGED FOR DISABILITY

To the Editor:—I was a first lieutenant in the Medical Reserve Corps from Aug. 11, 1917, to March 6, 1918, when I was honorably discharged on account of "disability existing prior to my entrance into the service, etc." I was not given an extra month's pay to set me up in the practice that I had given up. Now, Article III, Section 300, War Risk Insurance Act of Oct. 6, 1917, as amended June 25, 1918, provides that "officers and enlisted men or other members shall be taken to have been in sound condition when examined, accepted and enrolled for the service, and thereafter entitled to compensation under the act of disability." In other words, "legally no disorder can have preexisted in a person accepted for military service." Am I not therefore entitled to an extra month's pay as any man who is honorably discharged?

B. W.

Answer.—According to the Act of Congress approved May 24, 1917—the Selective Service Act—"the President is hereby authorized to discharge any officer from the office held by him under such appointment for any cause which, in the judgment of the President, would promote the public service; and the general commanding any division and higher tactical organization or territorial department is authorized to appoint from time to time military boards . . . to examine into and report upon the capacity, qualification, conduct and efficiency of any commissioned officer within his command other than officers of the Regular Army holding permanent or provisional commissions therein . . . and if the report of such board be adverse to the continuance of any such officer and be approved by the President, such officer shall be discharged from the service at the discretion of the President with one month's pay and allowances," for the payment of which application should be made to the Director of Finance. Pay of the Army Division, Pay and Mileage Branch, Munitions Building, Washington, D. C.

LINIMENTS OF SOLID CONSISTENCY

To the Editor:—Please describe a method of preparing a solidified liniment, giving the proportions of chemicals used to make a 5 pound mixture, how much capsicum, terebene, oil of eucalyptus, camphor, etc. —if I desired to use these drugs—would be necessary to add to 5 pounds of petrolatum in order to produce a decided effect without blistering, etc. Also, what can I use to give it a dark amber color?

N. B. Noll, M.D., Slovan, Pa.

Answer.—Linimentum camphorae, U. S. P., contains 20 per cent. of camphor in cottonseed oil. Petrolatum may be used in place of the cottonseed oil. The camphor is dissolved in the petrolatum by the aid of gentle heat, 1 pound of camphor being used to 4 pounds of petrolatum. Any quantity of terebene or oil of eucalyptus desired could be incorporated in the petrolatum, the latter being liquefied first by warming.

If an amber color is desired, dealers in petrolatum products will supply an amber petrolatum of the shade wanted.

The National Formulary, Edition 4, p. 103, gives a formula for linimentum saponato-camphoratum, or solid opodeldoc. This liniment is a solid and contains camphor, volatile oils, etc. No doubt this formula could be modified to include other medicaments, or entirely to replace the camphor and volatile oils. The same book (p. 164) contains a formula for petroxolinum spissum, or solid petroxolin, which might be used as a basis for the incorporation of drugs such as our correspondent mentions.

An ointment of capsicum is described in the British Pharmacopeia, 1914, p. 437. This is made by digesting 25 gm. of bruised capsicum fruit with a mixture of 10 gm. of paraffin, 75 gm. of petrolatum and 10 gm. of lard, and then straining the mixture.

ROACHES IN A SANATORIUM

To the Editor:—We are having a great deal of trouble at the present time with roaches throughout the building, and it occurred to me that you might be able to make some suggestions as to the best method of exterminating the roaches. We have used various sprays and powders with very unsatisfactory results.

L. F. M. ——, Sanatorium ——, New York.

Answer.—According to Farmer's Bulletin 648, United States Department of Agriculture, the most effective material for the extermination of roaches is a mixture of 50 per cent. of sodium fluorid and 50 per cent. of inert material, such as flour or starch. It is employed in the same manner as other roach powders, that is, by forcing into crevices, sprinkling around drain pipes, etc.

Milk and German Infant Mortality Rate.—With regard to milk, as, indeed, with regard to almost everything else, we have hitherto labored under a foolish Germanic delusion, which the war has happily exploded. We have actually believed that we owe the best research work and the elucidation of the most difficult problems in connection with milk to Germany. The vainglorious pretensions of that egregious people, their appropriating propensities which have led them to purloin and fake up as new discoveries made in other countries, and the flattering utterances of some short-sighted professors of our own who have studied for a few months in a German laboratory, and are proud of their gutteral attainments, have conduced to this misconception. In a recent work on "Milk," published in this country, I find that of 273 references appended to the chapters on the biologic properties of milk, 181 are to books and papers of German origin. Nothing could be more misleading. The Germans have engaged in all sorts of meticulous investigations, and have endlessly corroborated and contradicted each other; but, as regards all practical hygiene, and administrative questions relating to milk, we should stand just where we are today if Germany had never existed.—Sir James Crichton-Brown, *Journal of State Medicine.*

Medical Education and State Boards of Registration

COMING EXAMINATIONS

Alaska: Juneau, March 4. Sec., Dr. L. P. Dawes, Juneau.

Arizona: Phoenix, April 1. Sec., Dr. Allen H. Williams, 219 Goodrich Bldg., Phoenix.

California: Los Angeles, March 17-20. Sec., Dr. C. B. Pinkham, State Capitol, Sacramento.

Colorado: Denver, April 1. Sec., Dr. David A. Strickler, 612 Empire Bldg., Denver.

Connecticut: New Haven, March 11-12. Sec. Reg. Bd., Dr. Chas. A. Tuttle, 196 York St., New Haven; Sec. Eclectic Bd., Dr. J. E. Hair, 730 State St., Bridgeport, and Sec. Homeo. Bd., Dr. E. C. M. Hall, 82 Grand Ave., New Haven

Idaho: Pocatello, April 1-2. Sec., Dr. Ray H. Fisher, Rigly.

Illinois: Chicago, March 3-5. Mr. F. C. Dodds, Supt. of Registration, Springfield.

Indiana: Indianapolis, Feb. 26-28. Sec., Dr. W. T. Gott, 84 State Capitol Bldg., Indianapolis.

Iowa: Iowa City, March 24-26. Sec., Dr. G. H. Sumner, Capitol Bldg., Des Moines.

Maine: Portland, March 11-12. Sec., Dr. Frank W. Searle, 776 Congress St., Portland.

Massachusetts: Boston, March 11-13. Sec., Dr. W. P. Bowers, Rm. 501, No. 1 Beacon St., Boston.

Minnesota: Minneapolis, April 1-4. Sec., Dr. T. S. McDavitt, 741 Lowry Bldg., St. Paul.

Montana: Helena, April 1. Sec., Dr. S. A. Cooney, 205 Power Bldg., Helena.

National Board of Medical Examiners: Philadelphia, June 2-7. Sec., Dr. J. S. Rodman, 1310 Medical Arts Bldg., Philadelphia.

New Hampshire: Concord, March 13-14. Sec., Dr. Charles Duncan, Concord.

Rhode Island: Providence, April 3-4. Sec., Dr. B. U. Richards, State House, Providence.

ANNUAL CONFERENCE ON MEDICAL EDUCATION AND LICENSURE

The next conference on Medical Education and Licensure will be held on the Eighteenth Floor of the La Salle Hotel, Monday and Tuesday, March 3 and 4, 1919. On Monday morning the Council on Medical Education will hold its Fifteenth Annual Conference, the session to begin at 9 o'clock. The program is as follows:

Opening remarks, Dr. John M. Dodson, acting chairman of the Council on Medical Education, Chicago.

"The Year in Medical Education," Dr. N. P. Colwell, secretary of the Council on Medical Education, Chicago.

"The Needs of Medical Education as Revealed by the War," Brig. Gen. E. L. Munson, Medical Corps, U. S. Army.

"The Medical Enlisted Reserve Corps and Its Relations to Medical Education During the War," Capt. F. C. Waite, Sanitary Corps, U. S. Army.

"The Desirability of Units of the Reserve Officers' Training Corps in Medical Schools," Lieut.-Col. H. D. Arnold, Medical Corps, U. S. Army.

Discussion: Major-Gen. Merritte W. Ireland, Surgeon-General, U. S. Army.

Rear-Admiral William C. Braisted, Surgeon-General, U. S. Navy.

Brig.-Gen. F. A. Winter, Army Medical School.

Rear-Admiral E. R. Stitt, Navy Medical School.

On Monday afternoon there will be a joint conference of the Council on Medical Education with the Federation of State Medical Boards, the session to begin at 2 o'clock. The program is as follows:

"Hospital Standardization and the Intern Year," Dr. A. R. Warner, president of the American Hospital Association, Cleveland.

Discussion: From the Standpoint of the Medical School, Dr. E. P. Lyon, dean, University of Minnesota Medical School, Minneapolis.

From the Standpoint of the State Licensing Boards, Mr. Francis W. Shepardson, director of the Department of Registration and Education of the state of Illinois, Springfield.

From the Standpoint of the Hospital, Mr. Richard P. Borden, Trustee of the American Hospital Association, Fall River, Mass.

On Tuesday morning there will be a joint conference of the Federation of State Medical Boards with the Association of American Medical Colleges, the session to begin at 10 o'clock. The program is as follows:

"Relation of Teaching Methods to Licensure Examinations," Dr. Walter P. Bowers, secretary of the Massachusetts State Board of Registration in Medicine, Boston.

"Cooperation in Examinations by the National Board of Medical Examiners, State Licensing Boards and the Medical Schools," Dr. John S. Rodman, secretary of the National Board of Medical Examiners, Philadelphia.

Discussion by Drs. John M. Dodson, B. D. Harison, Isadore Dyer and Thomas McDavitt.

On Tuesday afternoon the Association of American Medical Colleges and the Federation of State Medical Boards will hold separate meetings including their business sessions. At the meeting of the Association of American Medical Colleges, the following program will be presented:

President's Address, Dr. W. J. Means, Columbus, Ohio.

"Lengthening the College Term," Dr. George Blumer, dean of the Yale University School of Medicine, New Haven, Conn.

"Premedical Requirements of Returning Soldiers," Dr. E. P. Lyon, dean, University of Minnesota Medical School, Minneapolis.

"Freedom in Medical Education," Dr. C. R. Bardeen, dean, University of Wisconsin, Medical School, Madison.

At the meeting of the Federation of State Medical Boards of the United States, besides the reports of standing committees and the annual election of officers, the program will consist of:

President's Address, Dr. David A. Strickler, secretary of the Colorado State Board of Medical Examiners, Denver.

"The Annual Registration of Physicians," Dr. Frederick R. Green, secretary of the Council on Health and Public Instruction of the American Medical Association, Chicago.

R. O. T. C. UNITS AT MEDICAL SCHOOLS

The Medical Department of the Army is interested in the establishment of R. O. T. C. units at medical schools as a means of building up a reserve corps whose members, when called from civilian life to military service, will be competent to perform the essential duties of medical officers in the Army without further training. Rapid mobilization of an army should be provided for, and the "firing line" of the Medical Department begins the moment that soldiers are assembled in camps.

For this purpose these men should have, in addition to the qualifications for civilian practice, at least the following qualifications:

1. A knowledge of military hygiene and sanitation.
2. A sufficient knowledge of army organization and methods to enable them to procure supplies and carry on the administrative functions of their positions.
3. A sufficient military training to enable them to command the soldiers of the Medical Department under their charge.

These requirements can best be met through training in R. O. T. C. units established in medical schools and in summer camps. It is believed that such training can be so arranged as not to interfere seriously with the course of study in medicine, and that the physical training and discipline incident thereto will be of distinct personal benefit to the students.

These general ideas were presented for consideration at a conference at Chicago, January 11, in connection with the meeting of the Association of American Colleges. The general plan was unanimously approved by this conference, and the opinion was expressed that a concrete plan along these lines would be approved by medical schools. The details of a definite program for R. O. T. C. units in medical schools are now being worked out and will be presented for the consideration of all medical schools at the conference on medical education in Chicago, March 3 and 4, 1919.

New Hampshire December Examination

Dr. Charles Duncan, secretary of the New Hampshire Board of Registration in Medicine, reports the written examination held at Concord, Dec. 28-29, 1918. The examination covered 11 subjects and included 70 questions. An average of 75 per cent. was required to pass. Of the 2 candidates examined, 1 passed and 1, an osteopath, failed. Two candidates were licensed through reciprocity. The following colleges were represented:

PASSED

College	Year Grad.	Per Cent.
Tufts College Medical School	(1910)	92

LICENSED THROUGH RECIPROCITY

College	Year Grad.	Reciprocity with
Boston University	(1890)	Mass.
University of Vermont	(1880)	Mass.

Book Notices

War Neuroses. By John T. MacCurdy, M.D., Psychiatric Institu Ward's Island, New York, with a Preface by W. H. R. Rivers, M.I Fellow of St. John's College, Cambridge. Cloth. Price, $2.50. I 132. *New York: G. P. Putnam's Sons, 1918.*

The author was sent to England in 1917 to study nervo disorders caused by the war, and this excellent monogra is the result of his observations in British hospitals. It one of the best-balanced contributions to the subject as y published, although it is to be regretted that the author d not have the benefit of a visit to France as well, for t French were quick to appreciate the war neuroses and prom in providing for them. Some of the matter in the book relatively out of date and should be revised. For instan the statement is made that "the term 'shell shock' has be officially adopted by the British War Office." In fact, t term has been officially abolished.

MacCurdy's classification is delightfully simple, as believes that the vast preponderance of cases may be divid into two types: anxiety states and conversion hysteria. T former resembles what frequently is termed neurasthe (though we believe it is more like psychasthenia), and t latter is ordinary hysteria, which the author qualifies as *co version* because an idea is carried over into a physical syn tom. Psychologically the essential mechanism is the sa in that the psychoneurosis is a subconscious means of esca from a situation which for some reason or other has beco insupportable. Anxiety states are more frequent in offic in the more intelligent, in those who (more or less unco sciously) long for death. Hysteria is more frequent in p vates, the less intelligent, and in those who desire a wou as a means of relief. Typical cases are reported to illustr the types and illuminate the pathogenesis. If the autho classification is simple, his descriptions and his explanati of the nature of the cases are equally clear. He succeeds making a complex subject easily understandable. The features make his monograph of permanent value. Althou the advent of peace has dissipated the majority of w neuroses, the principles of pathology, genesis and treatme so lucidly expounded, apply to the neuroses of civil li Unfortunately, however, the peace neuroses are apt to be mo complex and more difficult to treat than those of war.

Chapter VI is a very rational one on concussion, and wholesome reading for any practitioner because it so we shows the difference between the organic and the function cases. A short chapter on heart neuroses is also very goo and anticipates the general conclusion which has followe that most of the cases in soldiers of "disordered action of th heart" are not neurotic in the narrow sense but are to l regarded as of organic origin, either from some endocri disorder, disturbance of the vegetative nervous system involvement of the inherent cardiac mechanism.

Roentgen Diagnosis of Diseases of the Head. By Dr. Arth Schüller, Head of the Clinic for Nervous Diseases at the Franz-Jose Ambulatorium, Vienna. Authorized Translation by Fred F. Stodkin M.D., M.R.C., with a Foreword by Ernest Sachs, M.D., Associa Professor of Surgery in Washington University. Approved for Pu lication by the Surgeon General of the United States Army. Clot Price, $4. *Pp. 305, with 97 illustrations.* St. Louis: C. V. Mos Company, 1918.

Roentgenography of the skull has come to occupy an important place in the diagnosis of intracranial conditions. Schül ler has studied this subject from every angle, and presen his findings in a practical rather than technical manner his book will therefore appeal more to the clinician than the roentgenologist. Normal conditions of the skull are exce lently described and illustrated, and make it possible any careful observer to distinguish normal variations fr pathologic conditions. Chapter I reviews the normal re tions as to size, shape and structure of the skull at vari ages, as well as the different varieties of skulls. Chapte treats of the irregularities in the development of the sk the anomalies of size and shape in consequence of dis bances in growth of the skeleton, changes in structure bone in consequence of inflammation and new growths injuries of the skull. Chapter III, in addition to path changes in the brain that can be exhibited roentgenologically, takes up the changes in the skull produced by intracranial affections. In the appendix are discussed the changes that can be determined roentgenologically in the nose, ear, eye and teeth. The many excellent illustrations bring out clearly the various points described in the text. The extensive bibliography which follows the appendix cannot fail to prove of value. American roentgenologists have not been overlooked entirely, although some meritorious work done in this country on the roentgenologic findings in the skull in epilepsy receives no mention whatever.

SYPHILIS, PALUDISME, AMIBIASE: TRAITEMENT INITIAL ET CURE DE BLANCHIMENT. Par Paul Ravaut, Médecin des Hôpitaux de Paris. Préface du Professeur Fernand Widal. Paper. Price, 4 francs. Pp. 88. Paris: Masson & Cie, 1918.

In the one volume Ravaut considers syphilis, malaria and amebiasis, emphasizing their close relationship through their protozoal origin, through the fact that there is a medication almost specific for each, and through the many points of similarity that they present throughout their course and in their treatment. The author is an ardent advocate of the necessity for vigorous treatment in the early stages of these diseases, for in all of them the chances for a cure are best at this time, before the organisms have established themselves in visceral foci. He gives detailed outlines of his plans for intensive early treatment, together with numerous formulas. He also describes the methods of treatment to be followed in the later or chronic stages. Thus the text embodies monographs on the treatment of these three diseases, which have been so frequent and important in France during the war, and is a summary of the recent advances that have been made in the knowledge of their treatment.

A TEXT-BOOK OF GENERAL BACTERIOLOGY. By Edwin O. Jordan, Ph.D., Professor of Bacteriology in the University of Chicago and in Rush Medical College. Sixth edition. Cloth. Price, $3.75 net. Pp. 691 with illustrations. Philadelphia: W. B. Saunders Company, 1918.

New editions are often simply new impressions without any additions or changes. Dr. Jordan's work is a new edition in the true sense of the word because it brings all of the subject matter up to date. Because of the advancing knowledge of certain pathogenic bacteria, the chapter on the pneumococcus has been entirely rewritten and that on the meningococcus extensively revised. Those who have followed the large amount of literature concerning the pneumococci during the last two or three years will be astonished to find how briefly and compactly Dr. Jordan has summarized these numerous investigations. Of course, the literature of his subject has been greatly augmented by the recent epiemic of respiratory infections, and no doubt more extensive ddition will be required for the next edition of the book. There are also new sections giving brief summaries of our resent knowledge of infectious jaundice, rat-bite fever and rench fever. This is perhaps one of the best general introluctions to the subject of bacteriology that has been prepared. With excellent discrimination the author lays stress on the fundamental facts of interest to the beginning student and to the general reader. Those who find it necessary to go farther into the subject have the way pointed out for them by well-chosen bibliographic references.

PERSONAL HYGIENE AND HOME NURSING: A PRACTICAL TEXT FOR GIRLS AND WOMEN FOR HOME AND SCHOOL USE. By Louisa C. Lippitt, R.N., Assistant Professor of Corrective Exercises, University of Wisconsin. Cloth. Price, $1.28. Pp. 256, with 79 illustrations. Yonkers-on-Hudson: World Book Company, 1919.

This book aims to give the general principles of home nurs-ng to girls and women. It lays down practical instruction or the conduct of daily life and gives directions for preventng the spread of infection from cases of communicable disase. The reader is furnished with information as to what o do in cases of accident or sickness, and also concerning he use of a few simple home remedies. A better knowledge f the contents of this book will lead the women of the counry to better appreciate the advice and services of a physiian and enable them to understand the fallacy of many of he unscientific fads which are now so common. The book written in an interesting style and is well illustrated.

Social Medicine, Medical Economics and Miscellany

A Comparison of the Mortality Rates by Weeks During the Influenza Epidemic of 1889-1890 and During the Primary Stage of the Influenza Epidemic of 1918 in Twelve Cities in the United States

In *Public Health Reports* (Jan. 31, 1919) are published charts and tables whereby it is possible to compare the epidemic of 1890 with the recent epidemic of respiratory disease for twelve of the large cities of the United States. The 1890 figures are obtained from a compilation made by Dr. S. W. Abbott, secretary of the Massachusetts State Board of Health. The peak weeks of that epidemic are compared with the peak weeks of the present epidemic. As a basis for comparison, the annual mortality rate by weeks has been employed, since this affords a true picture of the mortality rates as affected by the epidemic. In the accompanying charts the mortality rates have been plotted for each of the twelve cities and for the twelve cities as a single population group. From the statistics and the charts, *Public Health Reports* concludes that:

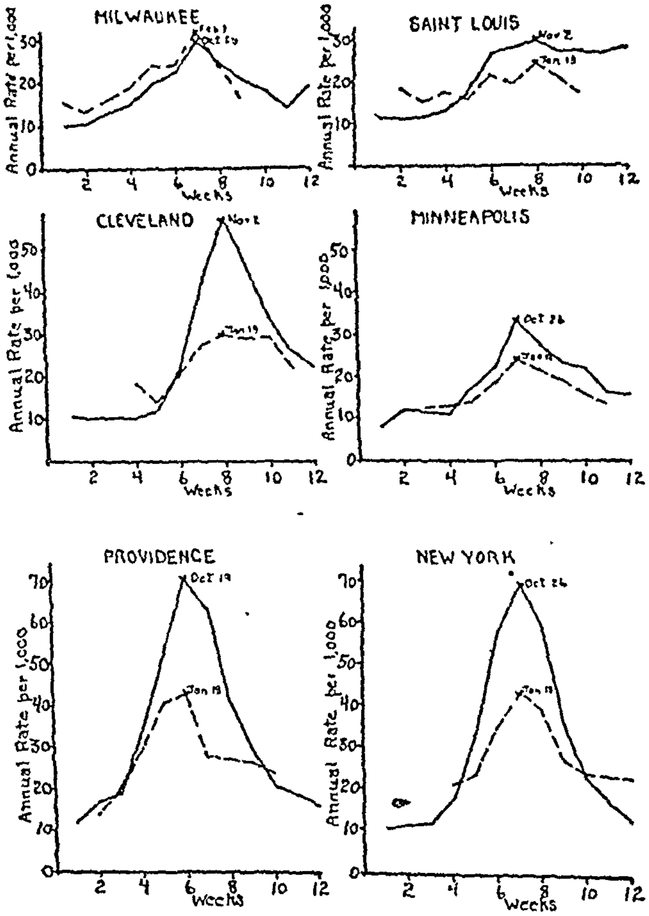

Chart 1.—Annual death rate per thousand population from all causes, by weeks, in the influenza epidemic of 1889-1890 (broken line) and 1918 (continuous line).

1. The mortality rate rose to a much higher point during the primary wave of the 1918 epidemic than in the epidemic of 1889-1890 in nine of the twelve cities. It is of interest to note that the rate was relatively low during both epidemic periods in St. Louis, Milwaukee and Minneapolis. If the mortality during the eight weeks of highest mortality is compared for the two epidemic periods in the twelve cities, considered as a single population group, it is seen that the annual mortality rate during the period Dec. 15, 1889, to Feb. 8, 1890, was 26.7, as against 35.2 for the period Sept. 29 to Nov. 23,

1918. In the peak week the rate rose to 55.6 in the 1918 epidemic as compared with 35.4 in the 1889-1890 epidemic.

2. While considerable irregularity in the curves as plotted in Chart 1 is evident, the curves of the two epidemics manifest, on the whole, quite a striking similarity for the same cities considered individually and as a whole. The length of the primary stage or wave—aside from recrudescences or continuance of relatively high, but not truly epidemic mortality rates—was quite similar for the two epidemics in all of the cities.

Spanish-American Medical Fellowship

Commenting on the publication of a Spanish edition of The Journal, the London *Lancet*, January 11, says: "The spirit of friendly cooperation has invaded medical circles on both sides of the Atlantic, and one of its latest developments is the proposed issue of a Spanish edition of the very ably edited *Journal of the American Medical Association.* The purpose of the issue is to promote the study of scientific medicine, and in so doing to further a closer international relationship between the great federation of English-speaking states in the North and the South. Last March President George E. Vincent, of the Rockefeller Foundation, approached the editor of the *Journal of the American Medical Association* with a suggestion on the subject, and at a subsequent meeting of the board of trustees of the Journal the publication of a Spanish edition was authorized. The first number is arranged to appear early in the present month, and the issue will be continued, for the time being, twice a month. All that is of more general interest and permanent value in the weekly Chicago edition will appear in the Spanish issue. Some 2,000 medical practitioners in Central and South America have been asked for their opinion as to the reception such a journal would meet with, and all the replies as yet received have been favorable. Up to the present Mexico and South America have been wont to turn to France and Germany for undergraduate and postgradute teaching, and to take from them their inspiration toward progress. This new venture may lead scientific men generally of the American Continent to realize their identity of interest and to open up opportunities for interchange of knowledge and of the results of research in various fields. We do not construe it in the sense of a rigid application of the Monroe doctrine. Certain standard English textbooks of medicine have already been translated into Spanish, and we should like to see this peaceful form of penetration continue and develop."

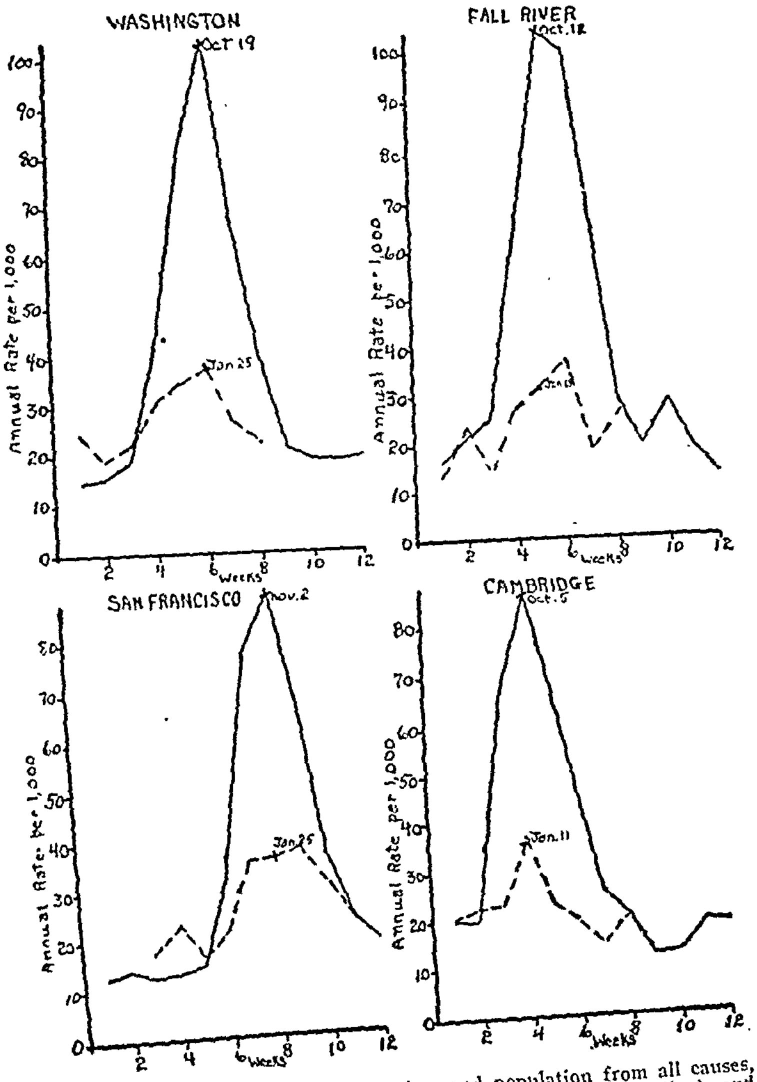

Chart 2.—Annual death rate per thousand population from all causes, by weeks, in the influenza epidemic of 1889-1890 (broken line) and 1918 (continuous line). (See page 517.)

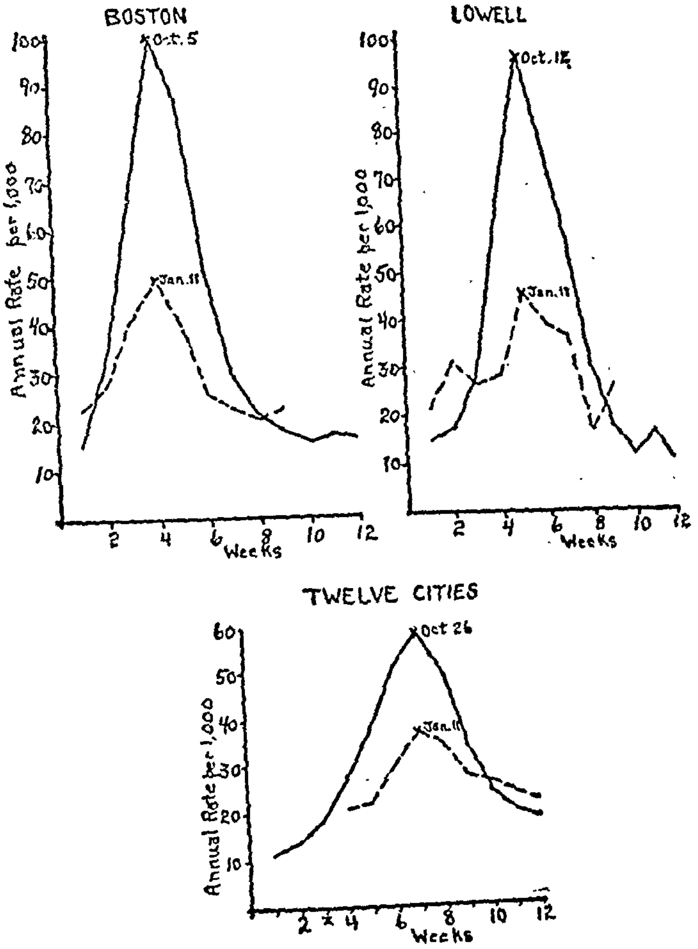

Chart 3.—Annual death rate per thousand population from all causes, by weeks, in the influenza epidemic of 1889-1890 (broken line) and 1918 (continuous line). (See page 517.)

Demobilization and Disease

The workmen and soldiers' council at Berlin, it is reported, recently has issued an appeal to the public, signed by sixteen physicians, pointing out the danger of dissemination of disease by the returning soldiers. Every soldier who feels sick is urged to go at once to some physician or hospital and remain under treatment so long as ordered. Those with vermin are urged to get deloused immediately. It says that those who do not heed these warnings will be doing great injustice to themselves, to their families, and to the entire people. The *Nederlandsch Tijdschrift*, which reports this item, adds that the measures which would have been taken with regular demobilization have been impossible of application in full, but the Demobilmachungsamt has provided for medical examination of soldiers on their discharge; when they are billeted anywhere they have to present a certificate that they have passed this examination. It is reported from Vienna that many soldiers being treated in hospitals for venereal diseases have run away from the hospitals. A large number of dispensaries, open day and evening, have been installed for free treatment of these diseases. The physicians returning from army service have charge of these dispensaries. Notices to the public give directions for reaching the delousing stations.

Medicolegal

Evidence in Action by Physician for Services

(Hobbs v. Hullman (N. Y.), 171 N. Y. Supp. 390)

The Supreme Court of New York, Appellate Division, Third Department, in reversing a judgment obtained by the plaintiff, a physician, for services rendered to the defendant's wife, holds that the nurse in attendance, who was not a registered or professional nurse, was properly permitted to give testimony of conversations between the physician, the defendant and herself as to the patient's condition and its cause. But it was error to permit the plaintiff to go into particulars as to the condition of the patient, and conversations between him and the husband with reference to the patient's condition and its cause. This evidence was inadmissible under Section 834 of the Code of Civil Procedure. This evidence was so clearly within the prohibition of the statute that a judgment influenced by it should not stand. It is against public policy to permit a physician to make such disclosures, even in an action to recover for his services. The evidence was unnecessary, and could have been offered only to prejudice the jury against the defendant, or to coerce him into a settlement. The court cannot say that it did not influence the result.

No Damages for Breach of Contract Endangering Public Health

(Hanford et al. v. Connecticut Fair Association, Inc. (Conn.), 103 Atl. R. 838)

The Supreme Court of Errors of Connecticut holds that there was no error in overruling a demurrer to the defendant's answer in this action brought by the plaintiffs to recover damages for an alleged breach of contract for a baby show to be promoted and managed by the plaintiffs. The court says that each of the two parties was to furnish and do such things as were deemed essential to attract a number of babies to the grounds and buildings controlled by the Fair Association. Presumably the babies were in some manner to be exhibited, and it was expected that at least 120 prizes would be awarded for such excellent and desirable traits as the babies might be adjudged to possess on an inspection and comparison. The defendant in its answer alleged that at the time the disease popularly known as infantile paralysis was epidemic in the city and throughout the state, being so widespread and so serious as to make assemblies of children, and especially young children, highly dangerous to the health of the children of the community, and by reason of these facts it was contrary to public policy to hold a baby show of the nature and at the time provided for in the alleged contract; that the defendant notified the plaintiffs that it wished to cancel the contract for that reason, and thereafter the contract was definitely and finally canceled for the reason named.

It was conceded that if a contract is contrary to public policy it is void. As it was admitted that the holding of a baby show under the circumstances narrated would be highly dangerous to the health of the community, it must follow that such a show would be contrary to public policy. This court is now considering the sufficiency of an allegation, not how that allegation could be proved. The allegation that the baby show would be dangerous to public health might be avoided by the plaintiffs by alleging, if such was the fact, that effectual precautions had been taken to prevent the communication of the disease from one child to another, or by setting up any other fact making it clear that no harm could result to the public from the show. But the court cannot regard the averment that the assemblage of a number of children as proposed would be "highly" dangerous to the public health other than as a fact which the plaintiff must answer, either by denial or matter in avoidance.

The court will not require the performance or award damages for a breach of a contract in which the public has so great an interest as the preservation of health, if the health is in fact endangered, any more than it would require one to be performed the tendency of which was immoral, or which interfered with the right of every one to earn a livelihood by a lawful occupation. The plaintiffs in their brief relied on certain cases which appeared to be actions brought by schoolteachers to recover salary when the schools had been closed by reason of the prevalence of some contagious or infectious disease in the community. But there is a difference between a contract to teach school and one to promote and manage a baby show. Teaching proper subjects can never be unlawful or contrary to public policy, though the assemblage of a number of children in one room might become very harmful. The teacher has usually no control over the attendance in his school. The baby show, however, would be highly dangerous to health, and this was just what the parties had agreed to promote and carry out for their mutual profit.

The plaintiffs contended that the defendant's undertaking was absolute and unqualified. But even though in this case the promise was absolute and unqualified, yet neither party contemplated that the show would be held if the public health would be endangered thereby, and therefore the contract impliedly contained a provision to that effect.

Two members of the court, however, think that the plaintiff's demurrer to the defendant's answer ought to have been sustained on the ground that it did not appear that the holding of this baby show had been prohibited by an order of the county or state health officials.

Prognosis in Heart Disease.—Three groups of 100 patients each, showing (1) pulsus alternans, (2) auricular fibrillation and (3) normal rhythm, have been studied by White with relation particularly to prognosis. A large number of each group has been followed for two or three years and the condition determined at the end of that time. Seventy-four per cent. of the patients with pulsus alternans, 48 per cent. with auricular fibrillation and 47 per cent., with normal rhythm have died. The higher grades of alternation of the pulse carry with them an especially high mortality, nearly 100 per cent., within three years. The cases with auricular fibrillation complicated by aberrant ventricular complexes seem to be very fatal (100 per cent. in the present series); those cases with ectopic ventricular contractions complicating the fibrillation have a mortality almost as high as the total of alternation, while uncomplicated auricular fibrillation has a surprisingly low mortality percentage.

Delay in Treatment of Cancer.—Of 103 cases of cancer considered in Farr's paper the average period from the onset of symptoms to the first consultation with a physician 3.19 months, and the average period from this time unt entrance into the hospital was 8.7 months. This gives a total of 11.89 months, practically a year, in the average cases, from the onset of symptoms to the entrance into the hospital. Of 101 of these cases classified, forty-four patients received good advice from the first physician consulted, forty-seven did not. Farr points out that even if every allowance is made for misunderstanding and ignorance on the part of the patient, the showing is appalling. Obviously, in the average case a considerable period of time is lost between the onset of symptoms and the first visit to a physician, and his advice is wrong in considerably more than half the cases.

Syphilitic Aortitis: Its Early Recognition.—The five cases reported by Brown show the frequency with which specific aortitis is confused with pulmonary disease, and that specific aortitis is not always a late syphilitic manifestation, in one case probably six to eight months after infection. Practically all physical signs may be present and the diagnosis will rest on substernal distress, a positive Wassermann test and the therapeutic test. A positive Wassermann reaction means syphilis, and even in the absence of all outward manifestations of syphilis, Brown says that the aorta should be suspected and active treatment instituted. A negative Wassermann test does not rule out specific aortitis, hence, a luetin test should be performed and the effect of treatment should be studied. When the more gross pathologic changes have taken place, treatment usually is ineffective.

Adenocarcinoma of Intestine with Metastases.—The metastases in the intestinal tract in Crowdy's case had some resemblance to pneumatosis cystoides intestini or intestinal gaseous cysts of swine and man. Metastases were also found in the peritoneal lymph glands, omentum, and hilum of the liver, indicating a dissemination through the peritoneal lymphatics and in this way resembling some cases of tuberculosis. The primary tumor apparently was of intestinal origin.

Ventricular Puncture in Diagnosis and Treatment of Meningitis.—Zingher urges that a prompt ventricular puncture is indicated in cases that show progressive meningeal symptoms and give a dry tap on lumbar puncture. Even less pronounced meningeal symptoms, such as slight but definite bulging of the anterior fontanel, tremors of the extremities and fever should lead to a ventricular puncture in cases that have given repeated dry taps in the hands of an experienced operator. Such early ventricular punctures are of vital importance in the successful treatment of cases of posterior basilar meningitis. In adults the persistence or aggravation of the clinical symptoms, associated with a persistently cloudy spinal fluid, which has become sterile after two or three injections of antimeningitis serum, often indicates the necessity for a ventricular puncture. In these patients, lumbar puncture may show a sufficient amount of spinal fluid; but the outlet from the ventricles is closed off, and the serum injected into the spinal canal does not reach these infected regions.

Ventricular punctures should be repeated daily or every other day; 20 to 50 c.c. of fluid are withdrawn and 15 to 30 c.c. of serum injected by gravity. The serum should be warmed to body temperature and a smaller amount always reinjected than the amount of fluid withdrawn. The interval of time between the punctures and the total number of punctures will depend on the rapidity in the reaccumulation of the fluid, as indicated clinically by the reappearance of a bulging anterior fontanel and on the result of the bacteriologic culture of the ventricular fluid. A lumbar puncture should be made at the time the patient is discharged from the hospital in order to determine the reestablishment of the communication between the ventricular cavities in the brain and the subdural space in the spinal canal. If the baby is breast fed every effort should be made to have the breast feeding continued while the patient remains in the hospital. Occasionally the diagnosis may be assisted in cases giving a dry tap, and before deciding on a ventricular puncture, by making a culture of the nasal discharge and finding the meningococcus present. Zingher states positively that cases of posterior basilar meningitis should be followed up for a period of years to determine the final outcome in those who recover after ventricular punctures and injections of antimeningitis serum.

Proper Method of Lumbar Puncture in Children and Adults.—Regan advises the median route for puncture in both children and adults. By reason of the structure of the lumbar spines in childhood, the only proper method of introducing the needle is in an exactly perpendicular direction to the spine, following in this way the direction of the spinous processes themselves. Any upward inclination imparted is unnecessary and increases proportionately the dangers of a "dry tap." This method of inserting the needle is applicable to children below the age of puberty.

In the adult, as a general rule, if the back can be well flexed, the needle should always be introduced directly perpendicular to the spine at an angle of 90 degrees. This direction will succeed except in a minor percentage of cases. If bone is encountered the instrument is then directed obliquely upward at an angle of 60 to 45 degrees, and this will always be followed by the disappearance of the bony obstruction and the entrance of the needle into the subarachnoid space, except in rare instances. When there is slight opisthotonos and the back cannot be flexed well or the lower limbs drawn up well, owing to rigidity, the spinous processes cannot be separated, and a perpendicular puncture at an angle of 90 degrees is commonly unsuccessful. Under such circumstances it is advisable to insert the needle in an upward direction, usually at an angle of 60 to 45 degrees. In the aged, spinal flexion is more difficult to obtain, hence it is usually advisable in such patients to give the instrument a decided direction upward.

Treatment of Dangerous Hematemesis.—The treatment advised by Bastedo is to have the patient very quiet, lying down, with head low, with a light ice-bag over the stomach and with plenty of fresh air; avoid unnecessary manipulation; give a hypodermic of morphin sulphate, 0.015 gram (one-fourth grain), with strychnin sulphate, 0.002 to 0.003 gram (1/30 to 1/20 grain). Immediately after vomiting give by mouth a solution of thromboplastin, kephalin, coagulen or epinephrin. In a case not of the portal congestion type, if the stomach remains distended and the bleeding seems to persist, perform lavage with tepid water, and follow this by passing in a solution of epinephrin, thromboplastin, kephalin or coagulen through the tube. In portal congestion cases avoid lavage. Prepare early for transfusion, and as soon as there are indications for it transfuse with careful watchfulness. If there is severe exsanguination, bandage legs and arms, raise the foot of the bed, bandage and put weights on the abdomen, keep up body warmth, and furnish fluid intravenously, subcutaneously and by rectum. If transfusion cannot be done, give Locke's or Ringer's solution containing 5 per cent. of acacia intravenously. Finally, have a surgeon at hand to share the responsibility, but do not operate.

To prevent recurrence inject subcutaneously every six or twelve hours for one or two days, 10 to 50 c.c. of human, rabbit or horse serum, or a solution of coagulose or euglobulin, or a single dose of 100 to 500 c.c. of human serum; or inject intramuscularly a solution of coagulen, thromboplastin or kephalin. If recurrence happens, resort to surgery, if necessary, preceding the operation by transfusion, (*a*) after the bleeding has stopped, or (*b*) if the bleeding continues but has become persistently small in amount.

Diagnosis of Mitral Stenosis.—In all thirty-six cases of mitral stenosis were diagnosed from a draft increment of about 15,000, twenty-four being "pure" cases and twelve associated with insufficiency. Of etiologic factors in the twenty-four cases of pure stenosis examined by Goodman, "rheumatic fever," chorea, tonsillitis and growing pains are the most important. In some instances, "rheumatic fever," chorea and tonsillitis appeared together. Cyanosis was observed fourteen times, pallor four times and in six cases the appearance was negative as far as these two phenomena were concerned. A presystolic thrill ending in the characteristic systolic shock was felt twenty-two times. In all of the twenty-four cases a murmur was heard, sometimes not in the erect posture but usually in the recumbent position, and always best in the ventral decubitus. A snappy first sound was heard typically nineteen times; in the five cases in which it was not heard a systolic murmur, accidental or without significance, muffled it. The second pulmonic sound was found to be accentuated over the normal fifteen times; in the nine cases not accentuated a diastolic murmur was heard. Hypertrophy of the heart was found in four cases. Irregularities were found but once, and this was an extrasystolic arrhythmia. The systolic blood pressure was sometimes quite high but the average of the twenty-four cases was 13.2 mm. Hg. The diastolic pressure was 78.

Method of Determining Volume-Flow of Blood.—An automatic and bloodless method of the volume-flow of blood is described by Gesell. The blood, without coming in contact with any foreign substance, is measured as it flows through a large vein, on its way to the heart. This vein, serving as a reservoir, is placed in the trough of the volume-flow recorder. By means of solenoids and electrical contacts operating a cut-off and an emptying-plate, the vein automatically fills and empties, the blood flowing on to the heart. The frequency of filling and emptying varies in direct proportion to the volume-flow of blood and is recorded by a signal magnet in circuit with one of the solenoids. The advantages of the method are said to be: (*a*) by calibration of the vein the procedure is made quantitative without the usual direct measurements of the blood; (*b*) it is automatic and therefore requires very little attention; (*c*) it is bloodless and therefore does not require the use of anticoagulants, and (*d*) it may be used over long periods of time without affecting the general condition of the animal.

Experimental Mammalian Polyneuritis.—The investigation reported on by Voegtlin and Lake aimed *primarily* at the production of deficiency polyneuritis in animals which were closely related to man and which could be used to better advantage in studies on experimental polyneuritis and the physiologic function of the antineuritic vitamin. Experiments were carried out on dogs, cats and albino rats. Cats seemed to respond to a deficient diet with the greatest regularity and for this reason most of the work dealt with this species. The authors succeeded in producing polyneuritis in cats and dogs as the result of an exclusive dietary of lean beef which was heated for three hours at 120 C. in the presence of alkali (sodium carbonate). Proof of this statement is furnished by the symptomatology, treatment and pathology of the disease noted, which are essentially those characteristic of beriberi. The authors are convinced that the disease is due to a deficiency of the diet in antineuritis substance and not to a deficiency in the other essential dietary components (amino acids, fat soluble vitamin, etc.). Exposure of the beef for three hours to a temperature of 120 C., without the previous addition of alkali, does not completely destroy the antineuritic power of this food. It is, therefore, concluded that the ordinary preparation of meat for human consumption does not lessen its food value in this respect.

Pulmonary Conditions Simulating Tuberculosis. J. H. Elliott.—p. 707.

Treatment of Diabetes with Tuberculosis.—The occurrence of diabetes and glycosuria in tuberculosis is, as a general proposition, considered comparatively infrequent by various writers. Among 31,834 cases of tuberculosis, collected from twenty-five tuberculosis sanatoria and hospitals in various parts of the United States, there were 101 (about *one third* of 1 per cent.) cases of glycosuria and fifty-one (about one sixth of 1 per cent.) cases of diabetes. Landis and his associates are convinced that some of the cases classed as glycosurias were undoubtedly diabetes, so that the percentage of diabetics may be assumed to be between one third and one sixth of 1 per cent. of all these tuberculous cases. The combination of diabetes and tuberculosis in the past was sufficient to render an almost hopeless prognosis. The treatment was unsatisfactory because in most instances the tuberculosis was considered paramount and the diabetes less important. Today it is known that it is vitally important to control the diabetes first of all, *at the same time* instituting other measures for the tuberculosis, such as rest, etc., as are compatible with the diabetic treatment. In tuberculosis, where so much is dependent on the ability to take and assimilate a diet of maximum value, the correction of any "specific deficiency in the power of assimilating food" becomes of first importance. The authors believe that it is absolutely necessary to accomplish this before it is possible to treat the tuberculosis effectively.

Twelve cases of pulmonary tuberculosis associated with diabetes were carefully studied. One case was incipient, five were moderately advanced, and six were far advanced. One revealed questionable activity, three slight activity, two moderate activity and six considerable or marked activity. The prognosis in six cases was doubtful and in six unfavorable. In seven of the twelve cases fasting was practiced at the start, in two for five successive days, in four for three successive days, and one for two days before the urine became sugar free. In all of the cases except one, fast days were ordered at various times during the course of the treatment. In five of the twelve cases the urine could be rendered sugar free on a standard carbohydrate-free diet plus various additions to this diet, including a moderate amount of carbohydrates. One patient, however, could be kept sugar free only by ultimately resorting to fasting. Nine of the patients exhibited amelioration in symptoms. In five of the nine cases just mentioned physical signs did not change while the patients were under observation.

As these results stand the authors say that it is possible for patients with tuberculosis and diabetes to partake of a considerably restricted diet over a period of some weeks and still show an increase in weight and strength, a fall in temperature, and a lessening of respiratory symptoms. Rest in bed, *rather than* exercise, as is advised in ordinary diabetics, is necessary because of the tuberculosis; and special care is necessary in order not to increase the fats too rapidly in the desire to bring up the caloric value of the diet, for fear of producing acidosis, as in several of our cases. The treatment is applicable in the presence of recurring hemoptysis, and in every case of tuberculosis of the lungs unless the patient is obviously hopelessly ill with the pulmonary lesion, in which case, the institution of the antidiabetic treatment would add only further discomfort.

Sunlight Treatment of Laryngeal Tuberculosis.—Mills and Forster are very enthusiastic over heliotherapy in laryngeal tuberculosis. The ultraviolet or actinic rays of the spectrum are the ones that produce the beneficial results. These are the chemical rays, the ones that cause tanning of the skin, and that have a bactericidal action. One of their patients worked out the details of this method. He preferred as being most efficient a reflector made of a metallic alloy of aluminum and magnesium. This alloy would reflect a very high percentage of the ultraviolet rays and at the same time absorb many of the heat rays, just the reverse of glass mirrors. The patient sits with his back to the sun. The sunlight is first reflected from a concave metallic mirror into the mouth of the patient, and on a metallic laryngeal mirror held in proper position in the throat. A glass mirror is used to view the larynx, for the purpose of observing that the light is being properly directed. Both the metallic condensing mirror and the glass observation mirror are attached by adjustable joints and supports to a frame, which can be conviently attached to the back of the ordinary chair placed in front of the patient. The patient will usually find it necessary to hold the tongue forward with a gauze handkerchief and must also have a glass of hot water at hand for heating the laryngeal mirror exactly as in ordinary laryngoscopic work. After a little practice most patients readily learn to observe their own larynx and to direct the light on the lesions.

Under the use of this method Mills and Forster have seen obstinate ulcers heal in some cases, infiltrations subside, painful lesions become painless, in fact a steady cleaning up and healing of tuberculous laryngeal lesions. They have not noted any bad effects from the use of this method. Occasionally at the beginning of treatment, they have seen infiltrations break down into small ulcerations, which then proceeded to heal under continued use of the light.

Obstetric Operations Under Nitrous Oxid-Oxygen Anesthesia.—Nitrous oxid and oxygen is looked on by McKesson as being an ideal anesthetic for obstetric operations. The advantages are: (1) Its transient effect, when removed, permits almost immediate resumption of normal labor; (2) its lack of depression on uterine and other muscle when properly administered; (3) its safety to mother and child; (4) the means at hand for perfusing the child with oxygen through the mother while the cord pulsates, factors which, McKesson says, should decrease fetal and maternal mortality and morbidity in operative obstetrics.

Urea Formation by Placenta.—It is evident from Hammett's observations that the placenta can form urea under certain circumstances. The processes leading up to this product are in question. Whatever the source of the urea found to be formed by placenta tissue, these results give evidence that this organ, as well as being excretory in function, is also actively concerned in the preparation of the nitrogenous by-products of the fetus for excretion. It is Hammett's idea that the fetus is only faintly able, if at all, to perform for, of, and by itself the functions of preparing its nourishment in assimilable form, or of breaking down its by-products into compounds ready for excretion; and that the placenta is interposed between mother and fetus to remove as far as possible these extra burdens from the maternal organism.

Metabolism in Multiple Exostoses.—A study was made by Krieble and Bergeim of the metabolism in a case of multiple exostoses. A loss of nitrogen was noted and ascribed, in part, to the associated hypermotility of the intestine. A retention of sulphur was observed and attributed to storage in the growing cartilage. The retention of phosphorus, calcium, and magnesium appeared to be within normal limits as did also the percentage excretion of these elements by way of the urine. These findings do not support the view of a relationship of this disorder to rickets or to any primary disturbance of general metabolism.

Vitamins in Green Foods.—Osborne and Mendel suggest that the green vegetables supply an important addition to the diet of man because the staples such as cereals, meats, potatoes, fats and sugar probably furnish *too small* an amount of either of these vitamins to meet fully the requirements of an adequate dietary. Therefore, care should be taken not to reduce greatly the quantity of green vegetables customarily eaten until more is learned about the actual requirements for these food factors and their relative abundance in the commonly used vegetables and green foods. Only then will it be safe to apply the results obtained in the laboratory to attempts to effect economies in the use of these relatively expensive food products.

Agglutination in Diagnosis of Glanders.—Povitzky has worked out a modification by which an agglutination reaction, clear cut in appearance, can be obtained in less than two hours with positive serum in dilutions up to 1:2,000 or higher. The strain of *B. mallei* used was isolated from a case of human glanders. The medium which has given the most satisfactory results is potato-glycerin-veal agar that is 2.5 per cent. acid to phenolphthalein. The test has been found valuable in the routine examination of horses. With this test nearly all early and acute cases can be detected and thus the spread of the disease can be prevented. The whole technic is described in detail.

Case of Mucor Infection.—The history of this patient was suggestive of pulmonary tuberculosis, but examination of the sputum disclosed a mucor. The man was a farmer, hence Ernst suggests that the infection may have been occupational as has been suspected in other cases; that is, from corn, on which the mucor finds a favorable medium for growth. The infectious character of the organism is shown by the appearance of a slow chronic abscess in the peritoneal wall of a guinea-pig, following an injection with an emulsion from a pure culture of the mucor.

Experimental Organizing Pneumonia.—Investigations were made by Wadsworth for the purpose of ascertaining, if possible, why one case of pneumonia should resolve, another continue unresolved, and still another undergo organization. Inasmuch as secondary infection might be conceived as a determining factor in organizing pneumonia, Wadsworth made a study of the lesions of human cases of organizing pneumonia to determine, so far as was possible by morphological and cultural study alone, the bacterial factors concerned. Following this, a series of experimental studies in dogs by tracheal injection of the lungs were made of the action of the pneumococcus alone, of the staphylococcus alone, and then especially of the action of the pneumococcus associated with the staphylococcus. The pneumococcus in pure culture gave rise in the dog to exudative processes which in all respects resembled those of man, and which, like those of man, underwent complete resolution leaving little or no trace of the disease. The staphylococcus in pure culture gave rise to circumscribed areas of bronchopneumonia in which resolution was delayed or was followed by some interstitial bronchial pneumonia. It was only in the diffuse exudative lesions of the dog's lung incited by the pneumococcus and the staphylococcus together that resolution was regularly delayed and typical lesions of intra-alveolar organization were seen.

Differentiation of Tubercle Bacilli.—From Frothingham's experiments it seems that brom cresol purple and litmus may be valuable indicators for differentiating types of tubercle bacilli.

Organs After Transplantation.—An intensive study was made by Loeb of many kinds of tissue and his findings are very interesting. The original article should be consulted. On the whole, Loeb says, the simpler structures survive after transplantation. The transplantation represents, in some respects, a struggle for existence between tissues, and this struggle leads to a selection of the more resistant tissues. This selective action is mainly responsible for the ultimate structure of transplants.

Method of Carrying Meningococcus Cultures.—Bronfenbrenner and Schlesinger succeeded in rendering liver-agar uniformly suitable for the growth of meningococcus cultures. The preparation of the medium is as follows: (1) Make a liver infusion using 1,000 gm. of fresh beef liver to every 1,000 c.c. of water (double strength). Collect the extract through a single layer of cheesecloth. Boil for five minutes, stirring continuously. Do not adjust the reaction. Strain through a single layer of cheesecloth covered with a thin layer of cotton. Sterilize at 10 pounds' pressure for ten minutes. (2) Make a three per cent. agar solution in water. Filter through cotton. Add 2 per cent. peptone and 1 per cent. sodium chlorid. Do not adjust the reaction. Sterilize at 15 pounds for thirty minutes. Primary meningococcus colonies grow very rapidly on such a medium, which is very important in searching for carriers. Pure cultures may be kept alive on slopes of this medium for several weeks by inoculating the water of condensation and tilting the tube every day or two.

Micro Plate for Bacteria Cultures.—In order to reduce to a negligible quantity the amount of medium used, Bronfenbrenner and Schlesinger substituted cultures in drops of medium for test tubes. This procedure does away with the necessity of using individual tubes for each test. The result is a great economy of time and labor formerly spent in washing, plugging, filling and sterilizing glassware. Furthermore, the micro plate simplifies the manipulations involved in a number of bacteriological and biochemical tasks to such a degree that even a slightly trained laboratory assistant can perform reliably a greater volume of work in a given time than a highly trained worker can do by means of "standard" technic.

Oxygen Tension in Its Relation to Meningococcus.—The experiments reported on by St. John suggest that the retention of moisture in the medium used for the cultivation of the meningococcus is probably a more important factor than the oxygen content of the incubation atmosphere. It is not necessary, however, to cultivate the meningococcus in closed containers, as the same end-result is obtained by giving more consideration to the water content of the medium and to the prevention of surface evaporation during incubation. This latter may be accomplished by exposing the incubator air to large surfaces of water placed in shallow pans. This simple procedure has been adopted by the Army Medical School, and better cultural results are obtained.

Use of Serum in Lobar Pneumonia.—Gould and Shaweker believe that they have seen some good results from the use of serum in the Type I cases of pneumonia, but they do not overestimate the results. In all cases the serum was given by the gravity method in high dilution at or slightly above the patient's temperature. The apparatus used is described in detail.

Development of Specific Serum Therapy in Pneumonia.—Redden claims that the etiologic factor in 98 per cent. of all lobar pneumonias is the pneumococcus. Eighty per cent. fall serologically into three groups called fixed Types I, II, III. Two is further subdivided into a, b and x. The remaining 20 per cent. is called Group IV and is made up of numerous distinct races. Group IV may be found in 80 per cent. of normal mouths. But the fixed types are found only in the mouths of those recently ill with such a type or in one who has been in contact with such a type case. This points to carriers of the fixed types as the chief epidemiologic factor. About 38 per cent. of all cases are Type I; about 30 per cent. of all cases are Type II; about 11 per cent. of all cases are Type III. Against Type I an immune serum has been produced which reduces mortality by three fourths. Against Type II a less potent serum which reduces mortality by about one half has been produced. The authors insist that all cases of pneumonia should be typed as early as possible in order to give patients the benefit of antiserum, if of Type I or II. Practically all cases which fall into these two groups can be given serum without danger. Even if one of the Type I cases shows sensitiveness to the serum, an attempt should be made to desensitize in order to make Serum I available. Serum should be given as early as possible and in 100 c.c. amounts at eight-hour intervals for at least three doses, intravenously.

Probably the action of the growing pneumococcus plays an important part in producing the local lesion. Grouping not only makes serum therapy available but aids in prognosis, the order of increasing mortality being IV, I, II, III. Experience points to crowded quarters, exposure to severe weather, and devitalizing labor as important predisposing factors in the development of the disease.

Administration of Arsenic in Syphilis.—The use of concentrated solutions of arsenical preparations in the treatment of syphilis is endorsed by Lockhart and Atkinson. Among 2,859 intravenous injections, there has not occurred a single case of thrombosis of the vein. There have been no early reactions of an anaphylactic character. There have been no reactions, late or early, which could be attributed to the method of administration. Owing to the small size of the needle the pain of introduction is less than where the larger needle required by the gravity apparatus is used and much smaller veins may be successfully entered. On three or four occasions the vein has been missed or completely penetrated, and solution has been injected into the surrounding tissue. This accident causes a good deal of pain, swelling, and disability, which, however, pass off in a few days without abscess formation or permanent induration. A microscopic examination of blood withdrawn from the vein into the syringe containing the arsenic solution shows the blood cells apparently perfectly normal even some hours after withdrawal. One hundred and forty-one patients were discharged from the hospital as outpatients during one month with their external lesions soundly healed. The average duration of their stay was sixteen days. They return for treatment as outpatients at weekly intervals until the full course is completed.

Agglutinative and Opsonic Action.—In order to determine whether the agglutination of red blood cells can be accomplished by the use of chemical reagents, Bond tested a considerable number of substances. The reagents which have so far given the best results have been liquid paraffin and a 5 per cent. solution of gum acacia in normal saline. Liquid paraffin, when used as a dressing for wounds, seems to favor phagocytosis and to promote the separation of necrotic tissue. Examination of the pus cells recovered from gauze soaked in 5 per cent. gum solution when used as a dressing for wounds also shows a high percentage of living phagocytes. Many other chemical substances, of course, when added in certain proportions to a suspension of washed red cells in saline, bring about a clumping which cannot be distinguished under the microscope from the agglutination produced by serum. Among antiseptic reagents, acriflavine, 1 per thousand solution in normal saline, gives this result in a striking manner. In the case of most antiseptic substances, however, the cells undergo rapid injury and eventual disintegration. This does not occur with gum solution and liquid paraffin.

Apart from its action on disintegrated cells, previous agglutination by paraffin or gum solution also opsonizes whole red cells under certain conditions. Washed sheep's red cells when present in considerable quantity are more toxic to the leukocytes of certain individuals than to those of others. If, however, these washed sheep's red cells have been previously shaken up with gum solution or liquid paraffin before incubation the leukotoxic effect is largely prevented. A mutual adhesion occurs between the red cells and the phagocytes and a number of red cells are ingested.

Some reagents, like mercury perchlorid, which, in dilute solution, agglutinate red cells, are themselves toxic to the leukocytes. Others, like acriflavine, which, in dilute solution, are not markedly leukotoxic, do not seem to promote the ingestion of the red cells. It is a suggestive fact that those reagents which do promote the ingestion of red cells by leukocytes, for example, liquid paraffin and dilute gum solution, are mostly inert substances; they both, in different degrees, protect the shed leukocytes from rapid devitalization. They both affect the density of the serum and alter the surface tension of the cell bodies which they envelop. They are not erythrocidal or hemolytic in character. Thus a 5 per cent. gum solution in normal saline agglutinates washed red cells, but cells so agglutinated are not disintegrated, they can be washed free of the agglutinin in normal saline, and can then be reagglutinated by the gum solution. Reagents, on the other hand, which hemolyze and destroy the red cells prevent ingestion, possibly because they bring about a rapid diffusion of the liberated endotoxin in sufficient volume to poison the leukocytes. These observations suggest that the phenomena of hemagglutination, as it affects the cellular elements of the blood, should be described in terms of both red and white cells.

Streptococcal Invasion of Cerebrospinal Fluid.—Six weeks after an ischiorectal abscess had healed, Marshall's patient began to have pain and stiffness in the neck. There was no antecedent trauma, and no account of personal or family tuberculosis. The left posterior cervical region was swollen, tense, and hot. Fluctuation could not be made out. The greatest tenderness was just to the left of the ligamentum nuchae in its lower part. The perineum revealed the scar of a boil. Rectal examination showed no induration to suggest tuberculosis. No active focus of infection was found. A muscle-splitting approach was adopted. Beneath the deepest layer was found an abscess under great tension; some 25 c.c. of thick creamy pus escaped, and at the bottom of the cavity was felt the bare roughened lamina of the fourth cervical vertebrae; a probe cautiously introduced was felt to pass completely around it. The release of tension caused considerable oozing. This was arrested by light packing, and the next day Carrel-Dakin treatment was established. The bone lesion was sterilized in fourteen days and gave no further trouble; slight and temporary stiffness of the neck resulted. The pus gave on culture streptococci and staphylococci; no tubercle bacilli.

Vaccine Treatment of Influenza.—Tottenham reports on the use of an influenza vaccine consisting of *B. influenzae*, 60 million; streptococci, 80 million; pneumococci, 200 million per c.c., as a curative treatment in all cases of influenza. On admission, the patient is given 0.112 c.c. of the vaccine; forty-eight hours later this dose is repeated, and afterward as often as necessary, at intervals of forty-eight hours. After the first dose the quantity of the vaccine may be increased, but this depends on the reaction to the previous dose. The treatment has been attended with success.

War Injuries of Larynx.—Harmer analyzes 245 cases. He calls special attention to the frequency of paralysis of the vocal cords after gunshot wounds of the neck. Appearing immediately after the wound, it is generally abductor in type in the early stages. There is little doubt in Harmer's mind that shock is chiefly responsible, for the following reasons: (1) The large number of cases reported. (2) Paralysis of other cervical nerves (excluding brachial plexus) are comparatively rare. (3) Other nerves are known to be paralyzed by shock. (4) Paralysis of the recurrent has occurred several times after ligature of carotid aneurysms, and is well known in many other operations of the neck. (5) Paralysis of the brachial plexus is common after wounds of the neck, and all its trunks are generally involved rather than one, as would occur if a direct injury were responsible. The mortality from wounds of the larynx is high.

In 512 cases of neck wounds, mostly treated in France, there were thirty-one deaths, two of which had received injuries to the larynx. On the other hand, 1,873 neck wounds were treated in English hospitals during the same period with only seventeen deaths. Of these 110 received injuries to the larynx and only one case ended fatally. These figures prove that the mortality is much greater at the front than at the base. In two thirds of the gunshot injuries of the larynx that survive for more than a week recovery is complete, and no ill effects are produced beyond alteration of the voice.

Hypnosis in Shell Shock.—The value of hypnosis in the treatment of shell shock is extolled by Myers. He urges that this treatment be given more extended trial.

Endameba Histolytica Carriers.—Among 400 healthy recruits in the Britsh navy from all over the British Isles, Baylis found that ten were carriers of *Endameba histolytica*. Of these, eight had never been out of the British Isles, and seven at least had never had dysentery. Experiments on kittens were tried with a view to obtaining evidence of the pathogenicity of the strains of cysts from the "new entries." The kittens failed to become infected, but this is not regarded as evidence for the nonpathogenicity of such strains.

Prevention and Treatment of Diabetic Coma.—This subject is reviewed by Cammidge, and he emphasizes the fact that treatment directed to one cause is not likely to control the symptoms, at any rate, more than temporarily, and that the only "cure" is to prevent all possible causes by so arranging the diet that (1) the patient's tolerance for carbohydrate, protein, and fat is not exceeded; (2) the total load of food is within his metabolic capacity; (3) the diet is correctly balanced, and (4) a sufficient allowance of inorganic salts is provided. The earlier in the course of the disease such treatment is commenced the better are the results likely to be and the less difficult will it prove to arrange a diet fulfilling the necessary conditions, but even with advanced cases a surprising improvement can be effected by careful dieting along these lines.

If speedy improvement does not follow these measures, alkaline injections should be tried. Small uncontrolled doses are useless; the only method likely to be of much avail is to employ massive doses and regulate their administration by repeated examinations of the blood by Sellards' method or by estimations of the carbon dioxid content of the alveolar air. The injections should be continued until it is clear that any acidosis, whether due to the diabetic condition or to uremia, has been neutralized by a return to normal of the titratable alkalinity of the blood or of the carbon dioxid content of the alveolar air. The copious diuresis that follows large intravenous injections will tend to eliminate other toxins, and bleeding from the opened vein to the extent of 10 or 20 ounces will also help in that direction. In most cases of coma a dose of bicarbonate of soda approaching 150 to 200 gm. (5 to 7 ounces) will most likely be required. It is dangerous to introduce this amount into the circulation at one dose, and the maximum that should be attempted is 50 to 60 gm., in the the form of a liter of a 5 to 6 per cent., solution, or 1½ ounces of sodium bicarbonate in 30 ounces of water. The solution should be sterilized, if possible, but precautions should be taken to prevent the formation of the caustic normal carbonate, which readily occurs on boiling. The solution should be injected by the gravity method very slowly, half to one hour being allowed for a liter, and it should be kept at or about the temperature of the body. It is usually necessary to repeat the injection in about six hours, and if need be it may be repeated again after twelve and eighteen hours. Cardiac stimulants are advisable at an early stage in all cases of coma or threatened coma. Digitalis, subcutaneously or by mouth, is probably the best, but strychnin, caffein, alcohol, ether, camphor, ammonia, and pituitary extract may also be useful. There is a natural disposition to administer oxygen to relieve the distressing symptoms of air hunger, but it is a useless procedure, except for the mental effect on those who are watching, for the difficulty in respiration has been proved not to be due to lack of oxygen.

Epidemic Influenza. S. West.—p. 44.

Disinfection of Railway Carriages, Public Vehicles and Dwelling Rooms.—For so-called prophylactic remedies in influenza, Duckworth has more faith in the action of quinin than in any other drug. He is convinced of the value of douching the head and face with water (as hot as can be borne) in cases of distressing influenzal headache associated with sinusitis. The relief afforded is, he says, very noteworthy. Duckworth recommends the adequate disinfection of railway carriages, public vehicles and dwelling rooms which patients, suffering from influenza, have been using.

Influenza as it Affects Air Passages.—The use of sprays or lotions during the acute stage of an influenzal sinusitis is, held to be harmful by Thomson because they are apt to disseminate the infection, and there is the risk of their carrying it to the ear. The routine use of a saline or alkaline nose lotion is uncalled for. It is better to prescribe menthol, one-half dram; tincture of eucalyptus, 3 ounces. A teaspoonful of this is put in a pint jug of steaming water, and the vapor is inhaled up and down the nose every two or three hours. It generally relieves pain, it frequently stimulates a free discharge and patients are satisfied that it "clears the head." Relief to the frontal and sphenoidal sinuses may be secured by packing the neighborhood of the middle meatus for a few minutes every day, with a pledget of cotton soaked in cocain (5 per cent.) and epinephrin. When the acute stage is past, a simple alkaline nose lotion may be employed. The inflammatory troubles of the pharynx and larynx are treated on ordinary principles.

Cardiac Complications of Influenza.—The principles of treatment suggested by Mackenzie for these cases should be devoted to increasing the health of the body, as a whole, in such a way as to increase the natural resistance to infection, to eliminate toxic influences, and brace up the whole man bodily and mentally. The best way to achieve this is by fresh air and judicious exercise in the fresh air. When all fever has subsided, MacKenzie encourages the patient to get up and go about quietly, leaving it to the patient to stop any exertion that produces fatigue. As he improves, the form of outdoor exercise which gives most pleasure is recommended. Injudicious exercise may do harm, but there is one precaution of a very simple kind which suffices to prevent any danger, and that is to instruct the patient to indulge only in an exercise so long as it gives pleasure and causes no distress or discomfort, and to stop or slow down as soon as the sense of exhaustion, breathlessness, or pain is experienced.

Influenza from a Clinical Standpoint.—A word of warning is given by Moore in regard to prescribing alcoholic stimulants in influenza. He says that the mental state in this malady is so excitable, so unstable, so impressionable, so neurotic, that the seeds of intemperance may be sown by following the unthinking advice to take wine or spirits as a stay in weakness. Moore is convinced that alcoholic stimulants are, generally, not only unnecessary but positively harmful in the treatment of influenza. If ordered at all, they should be given with, or in, food, and only for a limited time like any other powerful drug. In the septic bronchopneumonia, so often met with of late, "turpentine punch" proved a valuable remedy. Ten drops of turpentine on a lump of sugar (when it was possible to get it) added to a wineglassful of ordinary whisky-punch, was the form in which this antiseptic stimulant was exhibited.

*Mirror Writing. C. Mirallié and Denês.—p. 638.
*Preparing Orbit for Artificial Eye. F. Lagrange.—p. 641.

Resumption of Work by War Cripples.—Gourdon reviews the experiences at Bordeaux with 5,104 disabled soldiers under training for self-support. *Only thirty-four* were so severely crippled from loss of both arms and legs or both arms, that they were incapable of any work. Among the 30 per cent., of the others who were severely crippled in the arms, 37 per cent. had to learn a new trade or *readapt* themselves to their old trade. *This was the case only in* 23 per cent. *of the men crippled* in the legs. The men sometimes rebel against the effort to learn a new trade or business. This makes it specially necessary for the rehabilitation of *the crippled to be entrusted to competent* physicians and technicians whose advice will inspire confidence, and the example of reeducated cripples will encourage and inspire them. Special training schools for men crippled *in the arms* are indispensable; in ordinary trade schools where they compare their work with that of their sound mates they are apt to lose all their courage. Fully 62 per cent. of all the maimed were agriculturalists, and 85 per cent. of the farmers spontaneously resumed their *farm* work, but only 48 per cent., of the agricultural laborers. It is important in farm work to supply a jointed foot to the amputated, as this *does not* sink into the soft ground. Farm work is particularly advisable after trephining of the skull. These men are liable to be incapable *of* concentrating their attention for long at a time, and work in the fields gives them the peace and quiet which they require. Men crippled in the legs fall short of the turnout of the normal only by about 10 per cent. But these crippled in the arms can produce only from 35 to 80 per cent., of the normal turn-out. The great majority of the crippled can thus be trained for manual labor, reserving the commercial and administrative occupations for a small number prepared for them by their previous education. Partial amputation of the fingers or hand interferes very little with manual work. Long forearm stumps can be used without difficulty in a certain number of occupations. High amputation of the forearm or upper arm renders manual work difficult, and it is quite impossible after disarticulation of the shoulder.

Mirror Writing.—Mirallié and Denès report that a woman stricken suddenly with right hemiplegia and motor aphasia began at once to write with the left hand, beginning at the right side. Her writing was thus of the mirror type, and she never noticed that it was not her usual way of writing. Figures as well as words and phrases were of this mirror type, but when she added or subtracted figures, she began at the correct point, at the right. They regard the case as confirming the view that mirror writing is the normal form of writing with the left hand.

Preparation of Orbit for Artificial Eye.—Lagrange cuts a flap, about 2 mm. thick and 6 or 7 cm. wide by 7 or 8 cm. long, in the subcutaneous adipose tissue of the temple. This oval flap with a broad pedicle is utilized to fill up the cavity left in the orbit after enucleation of the eyeball. The flap can be worked under the conjunctiva or not as desired. The rectus muscles can be sutured together to hold it in place.

Bulletins de la Société Médicale des Hôpitaux, Paris

*Comparative Percussion. P. J. Ménard.—p. 973.
*Treatment of Influenza. A. Pissavy and R. Robine.—p. 976.
Advantages of Colloidal Lipoid Vehicle for Drugs. Hudelo, Montlaur and Drouin.—p. 977.
*Radiography of Aorta. A. Mougeot.—p. 983.
*Syphilitic Origin of Mikulicz' Disease. E. de Massary and L. Tockmann.—p. 987.
*Sugar Treatment of Tuberculosis. G. Rosenthal.—p. 988.
*Epidemic of Influenza. E. Joltrain and P. Baufle.—p. 991.

Comparative Percussion.—Ménard discusses the findings as they differ during forcible inspiration and normal expiration. If the dulness over the base of the lung, for example, becomes modified during forcible inspiration, he declares that this excludes pleurisy with effusion and pachypleuritis with adhesion of the sheets of the pleura. In pleurisy without effusion there is merely more or less reduction in the inspiratory variation of the percussion sound. The absence of any modification in the percussion sound during forcible inspiration, coinciding with a higher pitch of the sound and reduced elasticity of the chest wall, indicates impermeability of the lung or a severe pleural affection. The absence of any modification during forcible inspiration is especially important with chronic tuberculosis. In the superior lobe it indicates a grave anatomic lesion. In Ménard's extensive roentgen verification of the percussion findings, he always found this area superposed by opacity and lack of any change during coughing. In the other parts of the lung, the impermeability must be considered also in relation to the pleura.

Hexamethylenamin by the Vein in Influenza.—Pissavy and Robine relate that of their thirty-seven cases of influenza with complications on the part of the lungs, seventeen were treated with intravenous injection of 8 c.c. of a solution of hexamethylenamin containing 0.25 gm. of the drug per 1 c.c. One in this group died, while five died in the group of twenty treated with the ordinary measures. The injection was always borne without appreciable by-effects.

Roentgen Study of Aorta.—Mougeot gives two roentgenograms of the normal thoracic aorta injected with some opaque substance, and discusses the findings.

Mikulicz' Disease in a Syphilitic.—The typical lacrimal and salivary gland enlargement of Mikulicz' disease in the case reported subsided under treatment for syphilis. This recalls a case reported by the same writers in which chronic thyroiditis with abortive myxedema simulated general paresis in a syphilitic, and the whole set of symptoms was clinically cured by combined mercurial and thyroid treatment. These two cases show that syphilis may attack the glands more often than has hitherto been credited.

Sugar Treatment of Tuberculosis.—Rosenthal reports a number of cases which apparently confirm the indirect curative influence of subcutaneous injections of sugar solution and the still more effectual action when given by the vein. He gave a series of twenty intravenous injections of 5, 10 or 20 c.c. of a solution of saccharose (equal parts saccharose and water), never noting any local or general reaction. Tests of the urine, etc., showed an activation of liver functioning and of the digestive processes in general. The most convincing of the cases he reports was that of a soldier of 30 with a subacute exacerbation of bilateral tuberculous processes transformed in a few weeks into a torpid state evidently on the way to healing.

Influenza.—Joltrain and Baufle discuss the flaring up of the epidemic of influenza in October, and relate that a troop of soldiers from Indo-China nearly all had the disease lightly in the spring, but when the disease appeared again it spared this troop completely, while troops and civilians around developed it, and in the severer form of the second period. This suggests, they think, an immunizing influence.

*Sign of Incipient Exophthalmic Goiter. C. Lian.—p. 665.
Self Protection in Roentgen Work. L. Delherm.—p. 667.
Gun with Bent Bayonet for Immobilization and Traction of Fractured Femur on the Battlefield. L. Babin.—p. 669.

Sign of Abortive Form of Exophthalmic Goiter.—Lian announces that tenderness in the region of the thyroid is a sign of a tendency to exophthalmic goiter. The symptoms on the part of the heart with this abortive form of exophthalmic goiter may be mistaken for a cardiac neurosis. The tachycardia may be moderate, and occur only when standing or working, or under emotional stress. Predominance in the morning and slight maximal hypertension are not restricted to exophthalmic goiter. Only examination of the thyroid body and eyes will decide the question. In every case of tachycardia of doubtful origin, all the ocular signs of exophthalmic goiter should be sought with care, even when there is nothing to suggest exophthalmos or goiter. Sometimes only the behavior of the upper eyelid will give the clue. Certainty is attained by the pain experienced when the thyroid region is palpated or explored with the point of a pin. The patient's wincing and grimaces as the thyroid area is reached, render questions unnecessary. The pain is sharp, like a burn or deep prick. This painful area corresponds almost exactly with the outline of the thyroid or merely of the isthmus. A light stroking of the thyroid region started one patient to coughing. When the goiter is once developed, this sensitiveness vanishes. Hyperesthesia of the thyroid region seems to provide the Ariadne's thread which will enable us to lead out from the maze of cases of palpitations those who have incipient exophthalmic goiter. Lian has thus discovered eight of these *petits basedowiens* in his last thirty cases of puzzling tachycardia. A number of such will probably be found among the cases now labeled tachycardia from shell shock. The experiences related sustain the assumption of an infectious toxic origin for exophthalmic goiter in many cases. Acute articular rheumatism and typhoid probably head the list, but inherited syphilis must sometimes be incriminated.

The Support Immediately after Amputation. Roederer.—p. 409.
Pedagogic Anthropology. Godin.—p. 409.
*Malaria and Urinary Infection. Uteau and Piollenc.—p. 411.

Malaria and Urinary Infection.—Two cases are reported which warn that an infectious process in bladder or urethra may induce intermittent attacks of chills and fever which are liable to be mistaken for malaria and treated accordingly. This was the case here, the two soldiers having been taking courses of quinin, but after incision of a urinary phlegmon, or urethrotomy for stenosis, the supposed malaria disappeared permanently.

Vital Staining. F. Uhlmann.—p. 1665.
*Influenza and Psychoses. S. Notkin.—p. 1669.
*Malignant Tumors with Leukemia. E. Munk.—p. 1671.
*Medical Aspects of Foot Races. F. M. Messerli.—p. 1680.

Psychoses with Influenza.—Notkin reports two cases in which latent dementia praecox was whipped up into a pronounced form by an attack of influenza. In two other cases acute mania developed during the influenza. He had several other cases of psychoses developing during influenza, but he is convinced that there was always some more or less latent predisposition. The onset was stormy but in a short time essential improvement or complete recovery followed.

Leukemia with Malignant Tumors.—Munk analyzes what has been published on this subject, and reports the case of a woman of 59 who was under observation in the hospital for fifteen months. Pains in the left side led to the discovery of myeloid leukemia, and the left side was exposed to the roentgen rays. Later a sarcoma developed in the foot and another in the knee, and numerous nodules were found in various organs. In certain points, especially the chronic course, the case differs from Sternberg's description of myelosarcomatosis, and there was no tendency to green discloration of the marrow, which was pronounced in all the cases of myelosarcomatosis on record. There was no Bence-Jones albumose to be found, while the blood contained 60 per cent. myelocytes. The case thus had certain features of chronic leukemia and of Rustitzky's multiple myelomas, as well as of myelosarcomatosis, without fitting into the frame of either.

Medical Tests of Marathon Runners.—Messerli reports the findings in some foot races under the auspices of athletic associations and the military service. The preliminary examination enabled him to exclude certain runners whose heart would certainly have been unable to stand the strain without injury. The findings afterward emphasize the great importance of systematic regular training in exercises of the kind. The men trained in athletics bore the long runs up to 21 km. 800 m. without any cardiac or other disturbance. The army runners, on the other hand, who had not had systematic or long enough training developed abnormal manifestations on the part of the heart in 44.7 per cent. He advises shortening the course to 12 km. and insisting on systematic training for the *course de fond,* as this is highly useful and necessary from the military standpoint.

Deficiency Diseases.—Volpino reports the results of experimental research on pellagra, scurvy and what he calls monophagism, comparing his findings with those published by others. He is director of the state bacteriologic laboratory at Bergamo, and among the practical results realized was the active immunization of pellagrins against relapses and recurrence. This was accomplished by injection of progressively increasing doses of an aqueous extract of maize. Pellagrins in the first stage of the disease were selected, and the course was begun during the winter, as pellagra generally shows an attenuation in the winter. Fourteen patients were thus treated and twelve have been traced to date. Some of them had been totally incapacitated by the recurrences of the pellagra, but the immunization realized by the injections seemed to banish further recurrences. The cure has been complete to date in six and nearly complete in three others. The disease is stationary in another. These have all returned to their customary diet. One other is under specially favorable dietetic conditions and his health has been continuously normal.

An extract of spoiled maize induces a severe and complex reaction in pellagrins, but nothing of the kind is observed with the extract of sound maize. The severe reaction seems to indicate that pellagrins are in a state of hypersensitization. This assumption is sustained by the fact that guinea-pigs fed exclusively on maize for twenty or thirty days and then injected with blood from a pellagrin die in twenty-four hours, or at most in two or three days, while the blood from nonpellagrins does not affect them. Another feature found common to pellagrins and to the maize-fed guinea-pigs is that their serum contains ferments which digest the proteins of maize. The hypersensitization to the extract of spoiled maize and the ferment content of the serum fluctuate parallel to the manifestations of the pellagra, both practically disappearing as the patients recover from the pellagra. Both are evident in a slight degree in nonpellagrins who are habitual eaters of maize.

The phenomena observed in pellagra throw light on the loss of weight and of appetite from a too long continued uniform or one-sided diet—monophagism. A change to another cereal does not answer; the change has to be to some substance of quite different nature, potatoes or peas, when the experimental animals were running down from three weeks' feeding with corn or any other single cereal. The animal died on a change to rice or wheat, the same as if the corn alone had been continued. There is evidently, besides the lack of certain elements in the food, the presence of certain other elements which in time develop a toxic sensitizing action. In this, monophagism differs essentially from starvation and from avitaminosis. This doctrine of monophagism explains what is observed in pellagra and also in scurvy. Epidemics of the latter have been observed when there was abundance of fresh vegetables or potatoes. There seems to be a toxic sensitization of the organism from the one-sided diet, defective in certain elements and with an overabundance of others, working in a predisposing environment. Turnbull's experiments have demonstrated that certain hay-fever subjects seem to be sensitized against the proteins of certain cereals, so that by dropping bread and cooked cereals from their diet their state of anaphylaxis was much attenuated. But the most convincing proof, Volpino reiterates, of the correctness of his views is his success in immunizing guinea-pigs and pellagrins against return of symptoms by injection of an aqueous extract of maize.

Vaccinated Culture Mediums and Staphylococci.—Carpano cultivated the staphylococcus on the usual culture medium and then filtered out or scraped away the cultures, and sowed the medium again with the staphylococcus after this preliminary vaccination. It did not grow well on broth mediums thus vaccinated, and it did not grow at all on solid mediums. Crossed cultivation with other strains and with other common bacteria showed a reciprocal tolerance, the inhibiting effect being far less pronounced with bacteria such as are commonly associated with staphylococci.

Agglutinins and Coagglutinins in the Serum.—Vecchi and Sarti report that the results of the extensive research here described show that agglutination of typhoid and paratyphoid bacilli has scant diagnostic importance unless it occurs only above 1 : 100. Normal persons frequently display weak agglutinating properties, especially if they have recently been vaccinated against typhoid, as also the sick with other diseases entailing intestinal lesions.

*Operative Cure of Coxa Vara. L. Losio.—p. 635.
*To Center the Articulation. A. Lollini.—p. 645.

To Lengthen Shortened Limbs: The Osteotone.—Putti gives illustrated descriptions of the technic he applies to lengthen a shortened femur and means to stretch the soft parts to correspond. The bone is sawed lengthwise, then half way across at top and bottom of the lengthwise sawed portion. This enables the two halves to be slipped along on each other and lengthens the bone considerably. He does the lengthwise sawing in a sound part of the bone, not through the fractured portion. The sawing is done with a circular saw mounted transverse to the handle. The transverse sawing is done with the saw parallel to the axis of the handle. A Gigli wire saw might be used instead. The incisions in the periosteum are inverse to those in the bone, and the flaps are turned back. The stretching of the soft parts is done by means of two long screws implanted in the femur above and below the plastic operation. These screws are mounted on a straight bar parallel to the femur. This bar can be screwed longer or shorter as desired, thus bringing the screws in the bone nearer together or farther apart. This traction by double infixation can keep up a gentle but continuous traction, graduated day by day to conform to the traction desired and the lengthening realized. Four cases are described to show the harmlessness of this *trazione per doppia infissione*, and the fine results attained with shortening of one or more years' standing. The osteotone is much more convenient in every way than other methods of treating shortening with complicated pulleys, weights, etc. With the osteotone the man can be up and about, with crutches. In one of the cases reported a shortening of 9 cm. of three years' standing was reduced to 2 cm. by this means. It acts exclusively through the skeleton, and exclusively at that portion of the bone which is being lengthened, and it seems to be better tolerated than any other method of external traction. Diagrams are given showing the force applied in comparison to the stretching realized. In one case the integral lengthening of the limb was obtained in fifteen days. The vessels adapt themselves perfectly to the stretching of the soft parts but the nerves are less amenable sometimes. In one case there was pain in the sciatic nerve for a few days but it then disappeared spontaneously. In one case the plastic operation had to be done at the site of the old fracture, and pains in the femoral nerve compelled the removal of the osteotone before the full lengthening was realized.

Displacement of Ulnar Nerve to Shorten Its Course.—Bastianelli reports two cases in which the ulnar nerve at the elbow required suturing. By moving the stumps forward, to the front of the elbow, the course of the nerve was shortened so much that the stumps were readily sutured together. There had been quite a gap between them as they lay in their natural position. The two patients have not experienced any inconvenience from the altered position of the nerve.

Autografts of Fascia to Aid in Mobilization of Tissues.—Scalone gives the details of thirteen cases in which he applied an investing sheath to a sutured nerve or other tissues liable to develop adhesions. The investing sheath was cut usually from the fascia lata, only once from the aponeurosis near the field of operation. The operations were done for six different indications, including reconstruction of the aponeurosis destroyed by trauma, of tendon sheaths after suture or plastic operations on a tendon, and to prevent the radius and ulna from growing together again after synostosis had been broken up. In two cases the fascia flap was used to substitute the dura mater after a war wound of the skull.

Sciatica from Congenital Anomaly of the Vertebrae.—Rossi remarks that the roentgen rays have cleared up many mysteries but scarcely any more interesting than the symptoms from radicular neuritis of the sacral plexus resulting from a congenital anomaly of the fifth lumbar vertebra—what he calls sacralization of this vertebra. He has encountered twenty-two cases in roentgen examination of 800 spines, and others have reported similar cases, bringing to forty-six the number now on record. The resulting disturbances had been labeled rebellious bilateral sciatica, Potts' disease, coxalgia, or lumbago. The pains in the lumbar-sacral region or hip joint were aggravated by walking and fatigue of any kind, and were relieved by repose and lying down. The disturbances did not develop as a rule until between the ages of 20 and 35, although in one of his cases a child of 6 was affected. Sometimes they came on first after a trauma or acute polyarticular rheumatism. The complete ossification of the skeleton probably is responsible for their final development in some cases. The prognosis is generally benign although the disturbances may become serious and chronic. Recurrences are not frequent. If prolonged repose, electric and other medical measures fail to cure, a bone graft might be proposed to relieve the compression on the nerve. The outcome is generally favorable.

Treatment of Extreme Coxa Vara.—Losio extols the advantages of Codivilla's hinge method of osteotomy at the junction of the neck and shaft of the femur in treatment of coxa vara. But when the deformity is of a very extreme type, he prefers a curving osteotomy of the greater trochanter, and shows by a case reported in detail the superiority of this technic in these extreme cases.

Calculation of Center of Joint.—Lollini calls attention to the mathematical precision of the means with which he determines the exact center of the joint in measuring for an artificial limb. The illustrations show at a glance how the joint has its exact center determined by means of a curve drawn with a pencil fastened to the limb below as the joint is flexed and extended, the whole limb lying on the drawing board. The part of the limb above the joint has to be immovably fastened. The simplest means for this is to apply a plaster dressing and screw this hard shell to the board as he shows by illustrations of the thigh and knee thus arranged. The pencil fastened to the stump below the knee draws the arc of a circle as the joint is flexed. The radii drawn from different parts of this arc of a circle all meet at a point which is the exact functional center of the knee joint. The same principle can be applied to any joint. The arc formed by the play of the joint and recorded with an attached pencil gives the basis for drawing the radii, and their converging point is the center of the joint.

Does Influenza Confer Immunity?—Scoccia relates that epidemic influenza swept down on the Spezia hospital during the months of May and June and every one of the eighty nurses and attendants contracted the disease. Late in September the epidemic returned, severer than ever, but it spared completely all the nurses. Not one was affected. The conclusion seems obvious that the first attack left an immunity.

Plastic Motor Surgery.—Chiasserini describes three cases in which he reamputated the forearm to permit muscular control of the prosthesis. In another case he operated on the hand for the purpose.

Import of Extrasystoles for Prognosis.—Galli remarks that as extrasystoles may be encountered in both the well and the sick, while they may be missing from the graver clinical pictures, not much importance can be ascribed to them. He warns further that the subject's attention should never be called to them. If the subject has noticed them himself, he should be reassured and tranquillized at once. This is especially necessary in military circles as otherwise the man might cultivate this symptom and get discharged from service on account of it. Galli has seen men labeled myocarditis solely on the basis of these common extrasystoles.

Paraffin Drainage.—Soresi does not hesitate to call this method a new *principle of drainage* for surgical use. It is based on the fact that paraffin has no affinity for any other substance and is not affected by the organic fluids. Its name, *parum affinis,* suggests this. A strip of gauze impregnated with paraffin and carried into the depths of a wound holds aloof from the tissues and fluids, as it were, leaving always a free space between it and the tissues and fluids. This space, aided by gravity, is always sufficient for ample drainage of the secretions of a wound. No tubes, etc., are necessary. Three years of experience with war wounds treated with these paraffined strips of gauze have confirmed that, absolutely without exception, any quantity of secretions that may be produced are effectually drained away. Any paraffin will do. He heats a photographic bath tray, containing water, over an alcohol lamp. A smaller tray in the water tray holds the paraffin, and a narrow strip of gauze or cloth is held up by the two ends and worked back and forth in the melted paraffin until thoroughly coated with it, the entire length of the strip. If coarse gauze is used, the strip can be doubled before dipping. The strip can be dipped more than once if desired. The ends that had been held in the hand must be coated and dipped in turn also. Threads, rolls of gauze, and tubes can likewise be coated with the paraffin and used for special indications. Another way of applying the principle is by pouring melted paraffin directly into the wound. It settles down into the deepest recesses and crowds out the pus and loose foreign bodies, while drainage continues around it, and the hot paraffin has a stimulating action on the tissues. Soresi gives illustrations of the simple and inexpensive technic, and expatiates on the drawbacks of other methods of draining, and the advantages of the paraffin method, besides those already mentioned. He warns that the aid of gravity must be utilized to the extreme. His preliminary communication on this paraffin or petrolatum method was mentioned in The Journal early in 1916. His experience since then, he declares, has confirmed more and more the superiority of paraffin drainage over other methods in vogue to date.

Diversion of Urine with Wounds of Urethra.—Mosti reports eight cases to demonstrate the advantages of hypogastric cystotomy in case of injury of the urethra. If there are no signs of local sepsis, this may suffice alone, giving the urethral lesion a chance for spontaneous repair. A retention catheter should not be used except when the urethra has had to be incised, and then, only after the wound has begun to heal. Under other conditions the hypogastric diversion of the urine renders it unnecessary, while its use *may* entail serious injury.

*Chemical Study of Gastric Juice. L. Usobiaga.—p. 497. Conc'n.
*Stomach Disturbances after Salicylic Medication. R. Luis y Yagüe.—p. 501.

Chemical Research on Gastric Juice.—Usobiaga describes the various technics in vogue for study of the gastric juice, but declares that the Hayem and Winter incineration method surpasses all others in simplicity and the distinctness of the reactions. No complicated apparatus are required and the procedure takes very little time.

Stomach Derangement from Acetylsalicylic Acid.—Luis y Yagüe relates that during the epidemic of influenza many persons took acetylsalicylic acid or sodium salicylate, and numbers of cases were encountered in which severe stomach disturbances followed, sometimes with actual hematemesis. The drug was taken in the usual doses and intervals, and the disturbances began gradually and grew constantly worse, with sometimes sudden hematemesis; or melena was the first indication of the gastric hemorrhage. None of the persons thus affected had complained of stomach trouble but practically all had a history of a "gastric past," and the connection of the gastropathy with the medication was confirmed by the disappearance of symptoms when the drug was suspended, and their return when it was resumed. The greater number of cases coincided with the taking of the drug in the form of a tablet, swallowed without dissolving. No disturbances of any kind had followed when the drug had been given in the form of an enema. The mode of onset of the disturbances was quite different from that with an idiosyncrasy. Everything seems to indicate a direct local irritation of the stomach mucosa from the drug, acting like a caustic on a mucosa which happens to be a point of lessened resistance, or subject to erosions and particularly friable from any cause, and particularly with a latent ulcer. The normal mucosa seemed to bear the drugs without harm. The association of acetylsalicylic acid with sodium bicarbonate may promote the corrosive action as an alkaline medium accelerates the splitting of the drug and the liberation of the salicylic acid. The stomach history of every patient should be ascertained before prescribing either of these drugs, and they should not be given by the mouth in case of doubt, or at least the drug should be well diluted, and taken after eating, not before. The hemorrhage from the stomach cannot be explained by toxic action nor by the action of the influenza as no cases were encountered except those in which one of these drugs had been taken. Eight typical cases are related. The gastric hemorrhage was very severe in some of them, occurring with syncope, and returning in one case after only three or four tablets had been taken. Sodium salicylate was responsible in only two of the cases. The doses are not mentioned.

*Chorea. E. Odriozola.—p. 289.
*Tuberculin in Ocular Tuberculosis. A. Gardini.—p. 293.
Pathologic Anatomy of the Spleen. O. Hercelles.—p. 312. Cont'n.

Chorea.—Odriozola's experience has confirmed the assumption that chorea is a morbid entity with a multiple infectious origin, causing actual organic disturbance, probably in the cortex. It calls for repose for body and mind, removal of every possible focus of infection in teeth or tonsils and of irritation from helminths, otitis media, adenoids, phimosis, etc. The child should be kept out of school during convalescence to avoid relapses. In giving Fowler's solution the possibility of arsenical neuritis must not be forgotten.

Tuberculin in Ocular Tuberculosis.—Gardini reviews the testimony for and against tuberculin treatment of tuberculous lesions in the eye, and states that Dr. Campodónico has reported a case of tuberculous iridocyclitis which improved under two injections of tuberculin until almost perfect vision was restored. A year later the symptoms returned, still more severe, and fearing the loss of the eye from the hypertension, iridectomy was done, followed by another course of tuberculin treatment which proved as successful as before in clearing up the eye and restoring vision. Gardini emphasizes the necessity for small doses and avoidance of a febrile reaction, and long continuance of the tuberculin to ward off a relapse. There is no use in trying the tuberculin for ocular tuberculosis if there are already pulmonary lesions installed. Focal, local and general reactions show that we are on the right path, but warn to slow up some. The local reaction is of no moment except as an index of the patient's susceptibility. A focal reaction always occurred in the eye affected. He began with 1/10,000 mg. and very slowly and tentatively increased the dose to 1 mg. as the maximum, with four or five days' intervals. Three cases are described; the patients were two girls of 13 and a young woman. The tuberculous keratitis in the latter was of three years' standing and peculiarly tenacious. No benefit was apparent under the tuberculin treatment. The case teaches the lesson not to delay tuberculin treatment too long. One of the girls had had keratitis for two months and it improved to a clinical cure under the tuberculin treatment. In the other girl iritis with a solitary tubercle and posterior synechia, completely and permanently retrogressed under the three months' course of tuberculin treatment.

Vestibular Nystagmus. R. Argañaraz.—p. 169. To be continued.
*Continuous Drainage for Ascites. N. Tagliavacche.—p. 172.

Vaccination Against Typhoid in Argentine Army.—Mazza is chief of the laboratory service of the Argentine military medical department, and he relates that unprecedentedly fine results were obtained when the men were given two injections of larger doses instead of the three injections of former days. Even a single injection will answer if the vaccine is very fresh. It can be in an aqueous solution for the purpose, and the dose must be large. In case the vaccine cannot be absolutely fresh, lipovaccines should be used. He adds that the slow absorption of the lipovaccines, without reactions, and their indefinite keeping properties, without change, render them the ideal vaccine when it is desired to give merely one single, highly concentrated injection. The statistics he gives from the Argentine service confirm his statements in every respect.

Tuberculin Tests in Orphan Asylum.—De la Torre reports a positive response in seventy-one out of the 171 children tested. About 20 per cent. of the infants under 1 year gave a positive response, including one only 2 months old; 34.4 per cent. of those between 1 and 2; 42 per cent. of those between 2 and 5; 47.6 between 5 and 10, and 57 per cent. between 10 and 15. Of the total positive responses only fifty-two were obtained at the first test; eleven at the second, and the others at the third to the sixth application of the test. The first three tests were made by the skin technic, the others by Mantoux' intradermal method.

Malformations of the Uterus from the Obstetric Standpoint.—Pérez gives in this concluding instalment the various means for detecting malformations of the pregnant uterus, and describes the case of a primipara with a double uterus. The pregnant portion of the uterus lay slanting in the abdomen, while the empty portion, as large as a mandarin orange, opened into the cervix and impeded delivery as if a low tumor were in the way. The presence of the empty half entails abnormal conditions; in this case it seemed to have been responsible for the premature delivery. The woman entered the hospital at about the seventh month as there were small repeated hemorrhages from the uterus. She was given two enemas with laudanum and was kept in bed, but the next day the membranes ruptured and delivery followed spontaneously in a few hours. The child gave a cry, but soon died. The following day labor pains came on again, and finally scraps of decidua tissue were found loose in the vagina. This suggested the possibility of a double uterus, confirmed by examination under a few whiffs of chloroform. The bibliography on malformations of the uterus is appended, a total of 121 titles.

Continuous Autodraining of Ascitic Fluid.—Tagliavacche gives an illustration of what he calls a button-cannula. It is a broad tube, bent at a right angle, with wide openings at the tip. This tip is introduced into the abdominal cavity, while the flat flaring mouth of the tube, which is fitted into the subcutaneous tissue, keeps the tube in place, preventing its slipping into the abdominal cavity. In the case for which the silver drain tube was made, the ascites was the consequence of a syphilitic liver disease in a married woman of 43. The button rested on the aponeurosis, and the fluid drained through it best when the woman lay on her side. The case was a severe one, 12 liters of fluid having been removed just before the button-cannula was introduced, and the liver lesions were irreparable. The woman died about five months afterward, but her condition in the meanwhile had been rendered much more comfortable. The cannula was borne well. In a future case he would introduce it at a lower point in the abdomen in order to take better advantage of gravity.

*Experiences with Tuberculosis. J. V. Montenegro.—p. 205.
Mental Deficiency in North America. S. Rubiano.—p. 219.
*Uric Acid in the Human Organism. J. B. Millares.—p. 232.
*Treatment of Influenzal Pneumonia. A. Piga and L. Lamas.—p. 262.

Experiences with Pulmonary Tuberculosis.—Montenegro remarks that if he had preserved all the records he would have 40,000 cases on which to base his conclusions. But 20,000 adult cases are enough, and he here classifies this material. Over 18 per cent., were under 20; 40 per cent., between 20 and 30; 25 per cent., between 30 and 40, and 11 per cent., between 40 and 50. There were familial antecedents in only 26.53 per cent. of the 8,939 cases in which this was investigated. This group included 4.57 per cent. with tuberculous husband or wife; 11.6 per cent., tuberculous parents, and 8.9 per cent., tuberculous brothers and sisters. This low familial percentage is due to the fact that the familial group of infections so often prove fatal before adult age is reached. In only 62.36 per cent. was there history of some precursor disease, bronchitis in 28.67 and pneumonia in 10.41 per cent., tuberculous lesions elsewhere in 2.12 per cent. Early hemoptysis was noted in 48.16 per cent., and he insists that every hemorrhage from the lung in the young, if mitral stenosis and echinococcus disease can be excluded, is a sign of tuberculosis. It is not a grave symptom if not too profuse and if not accompanied by fever. He found a record of hemoptysis in 52 per cent., of the men and only in 48.88 per cent., of the women. The right side was affected in 36.79 per cent., of 11,485 cases, and the left side in 11.47; both lungs in 51.72 per cent., the sexes about equally represented in each group.

Uric Acid.—Millares' article obtained the prize offered by the *Progresos*. He presents the present status of our knowledge on the formation and elimination of uric acid in health and disease, recalling that the relation of uric acid to urea is a factor variable in each organism and independent of the food. The uric acid-forming property of different foods has a wide range, from thymus at one extreme to milk and eggs at the other. He adds that the normal uric acid content of the blood can be determined most conveniently and reliably by the Brugsch-Kristeller color method. It is based on the blue tint which develops when sodium carbonate is added to the solution of uric acid after it has been mixed with a solution of sodium tungstate. Details of the technic are given.

Treatment of Pneumonia.—Piga and Lamas insist that the first indication is to combat the toxemia, and they agree with Barbary that cholesterol is the best means yet at our disposal for this, but they do not specify how it should be given. They warn that the germs are in the blood although they seem to be only in the respiratory apparatus. The danger is in the blood; here the deadly germs are multiplying, and it is here they must be attacked. They consider mercuric chlorid as the best weapon to date for this, injecting it directly into the blood. Venesection may also be useful, injecting saline with epinephrin alternately with caffein to compensate for the blood withdrawn. Cold packs to reduce the temperature with medication to stimulate leukocytosis, in the grave cases, turpentine. Pleural effusions must be tapped, and they advocate the use of serum from the renal vein of goats, especially if there is reason to assume that the pleural effusion is of mechanical origin. Surgical measures should not be delayed if pus develops in the pleura. No technic nor doses are mentioned for any of the above.

Some Points in Microscopic Technic. P. J. Pujiula.—p. 221.
Referendum on Influenza. F. Tous Biaggi and others.—p. 225.

Treatment of Retention of Fragments of the Placenta.—Esquerdo has long been teaching that after the child has been delivered, the placenta and blood clots are to be regarded as foreign bodies which should be got rid of as soon as possible. He makes a practice of clearing out the uterus without delay, no matter what the conditions may be in regard to infection, after waiting at most twenty-four hours.

He clears the uterus but warns against using the curet for the purpose. Rubber drain tubes are placed to insure proper drainage, and the patient can then be left to the care of the nurse. He proceeds to clear out the uterus if all the placenta has not been expelled within twenty-four hours after the childbirth or abortion, or even earlier if hemorrhage or fever indicates that the fragments of the placenta are inducing irritation. When dilatation does not have to be forcible, there is no need for general anesthesia. He has not done any tamponing afterward for twelve years, and regards the whole procedure as so harmless that he does not hesitate to practice it even in incipient septicemia and peritonitis. He is convinced that it is the only means to ward off or control salpingitis.

*Echinococcus Cyst of Liver. J. A. Presno y Bastiony.—p. 675.
Gallstone Cholecystitis at Fifth Month of Pregnancy. E. Stincer.—p. 681.

Echinococcus Disease of the Liver.—Presno remarks that echinococcus disease is quite rare in Cuba. The case he reports is unusual further in that the echinococcus cyst formed a pedunculated tumor which was easily removed by cutting out the pedicle from the liver tissue. The patient was a Syrian who had been living for several years in Egypt. The tumor was supposed to be a movable kidney, as he had had nephropoxy done once and it was assumed that the kidney had worked loose, but an incision in this region showed it still in place. A median laparotomy then cleared up the case.

*Puerperal Gangrene of Uterus. E. Zarate.—p. 439.
Fibromas of External Ear. R. Becco.—p. 444.
*Simple Ulceration of the Stomach. L. A. Huerta.—p. 446.
Forceps and Version as Aid to Pubiotomy and Symphysiotomy. T. A. Chamorro.—p. 448.

Puerperal Gangrene of the Uterus.—Zarate cites Beckmann's compilation of forty cases of gangrenous metritis and reports a case from his own practice, the first published in Argentina. It seems to be rare in France, but Beckman's compilation included twelve cases in three years in one hospital at Petrograd. Fully 90 per cent. of the cases on record were in Slavic women. The sloughed off wall of the uterus is usually expelled about the close of the third week. The extreme sensitiveness of the uterus, the change in color, the fetid odor of the lochia and the small rapid pulse are the only clinical signs of the dissecting metritis at first. The mortality according to Beckmann was 28 per cent., the deaths occurring from perforation or septicemia. Intra-uterine treatment is contraindicated. In Zarate's case the sloughed off strip measured 4 by 15 cm. The odor was cadaveric, but as soon as it had been expelled the temperature and pulse returned to normal and clinical recovery was soon complete. The patient had borne nine children but only one and the fruit of the present pregnancy were viable. The others died soon after birth. Delivery had been instrumental in all. The microscope showed an enormous number of associated germs in the connective tissue of the cast-off sequester. These germs had evidently liquefied the interstitial tissue, and this facilitated the elimination of a large mass of muscle relatively only slightly altered.

Simple Gastric Ulceration.—Huerta presents arguments to prove that every case of Dieulafoy's exulceratio simplex should be sent to the surgeon at once without wasting time on medical measures. If this were done there would be no deaths from this affection. It always begins with rupture of an arteriole, but the secretions, the peristalsis and the fluid in the stomach prevent clotting to block the opening in the arteriole, or conditions may interfere with its retracting to close the opening spontaneously. Even although the patient may be absolutely still, this does not ensure conditions in the stomach allowing the plugging of the hole by a durable coagulum. In a case described, a man of 39, always healthy except for a well treated syphilis in 1913, was taken suddenly with hematemesis without pain. He kept still in bed with ice to the stomach, but twelve hours later the hematemesis returned, losing 1.5 liters of blood, and a tender point was evident in the epigastrium. The vomited blood was red, with black clots, no cough or froth, and the diagnosis of exulceratio simplex was confirmed by the operation which followed at once. An incision 10 cm. long in the anterior aspect of the stomach showed nothing abnormal until the stomach was everted, when three bleeding vessels were located in the posterior upper region of the stomach. Each was ligated with a crown of silk stitches around the bleeding points, 2 or 3 cm. apart. The patient has been in robust health during the years since. Huerta remarks that up to 1912 there had been only fourteen operative cases of this affection published. Then Castro reported the first case in Argentina.

Pressure Atrophy of Bone and Cartilage. Y. Tanaka.—p. 491.

Determination of Milk Sugar in Milk.—Miura describes a technic which facilitates the removal of the albumin in the milk, and determination of the sugar content.

Influence of Lipoids on Solubility of Haloid Salts.—Yoshitomi reports that bromids otherwise insoluble in ether, become dissolved under the influence of organic lipoids or lecithin. This influence is even more pronounced on the iodids, but less so on the chlorids. Iodids are also dissolved by benzin but not the bromids.

The Japanese Liver.—Kudo has made a special study of the liver from 165 Japanese cadavers and tabulates the findings. He adds that no comparison can be made between his findings and the liver in other races as he does not know of any systematic research of the kind in other countries with which they can be compared. His article is profusely illustrated.

Reform in Medical Education.—Rijnberk recently summarized Schwalbe's suggestions in this line. (See abstract on page 317 of THE JOURNAL, Jan. 25, 1919.) He here describes how Schwalbe proposes to gain time for the new branches he insists on, without lengthening the course. He suggests that the natural sciences, physics, etc., in the preparatory school should be given in special courses restricted exclusively to what is needed as a basis for the study of medicine, and no more. The course could easily be arranged with this in view. The course in physics should be restricted to the main points, and no practical exercises in physics should be expected of the medical student. All this leaves more time for chemistry, and a thorough grounding in this is necessary for a just conception of metabolism in health and disease, for dietetics, hygiene, legal medicine, therapeutics, etc. Laboratory work in chemistry is necessary. Botany, zoology and comparative anatomy he would discard altogether, and in place of them have biology, including heredity and paleobiology taught by a medical man.

The independent dissecting of cadavers he would also banish from the clinical years of the medical course. The knowledge derived from this work as at present conducted is not sufficient to enable the student to make independently a medicolegal necropsy, and he learns just as much in regard to the pathology of an organ when the professor takes it out of the cadaver before his eyes, as when he takes the organ out himself. Schwalbe urges further considerable cutting down in the practical laboratory work in bacteriology, including serology. The students cannot master the technic enough so they can go on to apply it independently. The cursory instruction in this branch can therefore be restricted to giving the students an insight into the methods of this special branch. The theoretical courses should also be reduced in number, the so-called general and special pathology, etc. A good textbook on the subject, studied quietly at home, is much more useful than the time-wasting and, from the nature of the subject, the dry theoretical lectures on these topics. When the medical student is ready for the final "candidate year," Schwalbe would have anatomy given less time and attention than is the rule now. He advocates breaking with the old tradition that the student must make his own preparations of all the nerves and muscles in the body. Schwalbe remarks, "Any one entering a dissecting room today can imagine himself transported back to the days of Vesalius. The students working so zealously to trace back to their first origins and final terminals, all the muscles, nerves and blood vessels, give the impression that they are striving to make discoveries in anatomy, as if the location and the course of the nerves, etc., were being investigated for the first time." In order to give the students a good idea of the relations between the muscles, joints and bones, he advocates demonstrations on the living body as anatomy is taught to students in the art schools. Also with roentgenograms and moving pictures. "In the dissecting room, let the attention be concentrated on topographical anatomy, especially of the cavities."

Rijnberk comments on all this that none of his readers probably will agree with Schwalbe in all points. He himself does not. "But it is certain," he adds, "that every one will find something in Schwalbe's remarks which appeal to him to some extent. The spirit of the university is always conservative, holding back from innovations. And in this lies its strength, but at the same time a danger. Life goes at a rapid pace nowadays. If the professors do not adapt themselves to the new needs and take into account the new demands on the profession, the training for which is their task, they fall short in the fulfilling of their duty. And there is no doubt that medical education as it now is conducted—good as it is in a certain sense—yet in many important points it does not answer its full purpose. With more exertion on the part of teachers and students than is necessary, yet it fails to attain all that might be attained, as every one knows who has given any thought to the matter in relation to practical needs."

Causes of Death with Cancer.—Meursing seeks to answer the question what people with cancer die of. He is prosector at the Pathology and Anatomy Laboratory at Amsterdam, and states that at 4,330 necropsies in the last nine years he found a malignant tumor in 602. The hospital with which the laboratory is connected does not take gynecologic, mental or eye cases, so that these groups are not represented among the cadavers. Of the total 14.4 per cent. cancer cases, the youngest age represented was a man of 21 with a liver cancer. In twenty-three cases there were two cancers, both possibly primary. The total of cancers was thus 625. About 25 per cent. had succumbed to cachexia; 2.4 per cent., to hemorrhage, mostly gastro-intestinal cases but there was one bladder case, and in four cases the fatal hemorrhage had occurred from a metastatic nodule on the surface of the liver. This suggests the necessity for caution in palpating the liver. About 5 per cent. of the intestinal cancers and 3.6 per cent., of the gastric cancers entailed fatal hemorrhage. Ileus, suffocation or pressure on the spinal cord were other causes of death, thus, a total of 38 per cent. for which the tumor itself was directly responsible. In the fifteen bladder cancer cases there were papillomas also in the bladder in three, that is, 20 per cent.; and in the stomach in eight of the 218 gastric cancer cases, that is, in 1.2 per cent. In the noncancer cadavers he found bladder papillomas only in 0.23 per cent., and stomach papillomas only in 0.36 per cent. These figures show that in 50 per cent. of the stomach papilloma cases malignant disease developed, as also in 30 per cent. of the bladder papilloma cases. Pulmonary embolism from three to thirteen days after the operation was the cause of death in 1.3 per cent. of operative cancer cases, and in 0.7 per cent., of the total cadavers. In about 4.7 per cent.. of the cancer cases death was due to pulmonary tuberculosis, while this was the cause of death in 22 per cent., of the total 4,330 necropsies. There was thrombosis in 5.2 per cent.; in 8.5 per cent. of the cancer cases.

Diet in Pregnancy.—Keyzer protests against some recent statements to the effect that the Prochownik diet for pregnant women has a tendency to make the woman weak while not facilitating the birth process. His experience with it has been extremely favorable. He recalls that Prochownik introduced this special diet exclusively for women with contracted pelvis, and this is its special field. Keyzer describes a particularly instructive case in which a multipara with contracted pelvis had always had extremely difficult deliveries until this diet was systematically followed at each pregnancy and approximately normal obstetric conditions were realized thereby. At a later pregnancy she neglected the Prochownik dietetic restrictions, and delivery was very difficult, the child's arm being broken in the procedure.

Influenzal Suppurative Process.—A woman of 59 was apparently recovering from influenzal pneumonia when she developed suppurative mastitis, followed in a few days by paralysis of the legs and other symptoms indicating some severe process at about the eleventh thoracic vertebra, with sudden death two days after the onset of the paralysis.

Trench Fever, etc.—Wolff's article was prepared at the request of the Netherlands public health authorities, and presents the present status of our knowledge in regard to trench fever, P. U. O., febris wolhynica, five-day fever, and alternating fever. His references are mostly to German weeklies in the last two years, with the British, and the American report on trench fever.

Blastomycosis of Central Nervous System.—Flu thought at first that the symptoms of the Chinese man were those of typhoid, especially as agglutination was decided at 1:400. Two days later meningitis seemed more probable, but lumbar puncture soon revealed blastomycetes in the spinal fluid, and necropsy disclosed foci of blastomycetes in the brain substance and in the pia of both brain and spine. The primary invasion seemed to have been at the base of the brain, and no blastomycetes were found elsewhere in the body except in the tonsils and mucosa of mouth and palate. It is plausible to assume that the blastomycetes made their way by the lymphatics from the tonsils to the base of the brain. They did not seem to cause any inflammatory reaction in the nervous tissues.

Water Supply Suggestions.—Eijken's advice in the specific case of pollution of the river water from a distillery is to drain the waste waters from the distillery by a separate pipe into the sea or else condense the waste into solid matter which can be used for fertilizer or burned to produce potash. In a second article he relates that in Java wells are frequently used of the Norton type, that is, wide iron pipes are sunk in the ground to a depth of about 48 feet. The lower 30 feet are perforated, and the water is pumped up and can be conveyed to a reservoir. He has recently simplified this method by sinking the pipes into existing wells and then filling up the wells with gravel nearly to the top, concluding the filling with sand. The ground is not suited for the Norton wells in many places, and he is confident that these gravel wells will be found of great service on plantations and elsewhere where it is impossible to secure reliable drinking water by other means. The diameter of the well can be enlarged as the need for water increases.

Vitamins in Coconut Oil.—Jansen's experiments were made on young rats. The outcome shows no growth-producing influence, and hence he assumes that coconut oil is poor in fat-soluble vitamins.

Is Vitamin Identical with Secretin?—Jansen's experimental research answers this question in the negative.

Agglutination of Flexner Bacilli by Normal Serum.—Flu reports positive agglutination at from 1:75 up to 1:900 in all but fourteen of 107 normal persons whose serum was tested at Weltevreden in Java. The tests with the Shiga-Kruse bacilli were negative in all but four of the same group.

Prevalence of Intestinal Parasites in Natives of Java.—Flu stated some time ago that he believed flies had some part in the distribution of amebas, and recent investigation of 941 inhabitants of native villages has confirmed this assumption. As the conditions for sanitation are extremely unfavorable in the native homes, it is evident that flies take a great share in the spread of ameba enteritis. This at the same time explains how the disease can spread to the homes of Europeans near by, although the latter take every precaution to have good drinking water. He found cysts of the tetragena (*Endameba histolytica*) in 10 per cent., accepting as such only those cysts 10 to 15 microns in diameter, with from one to four nuclei and the rodlike chromidia in the protoplasm characteristic of the tetragena. The prevalence of ascaris in 50 per cent. shows that opportunity for contamination with feces is present in excessive degree, and this renders the outlook for amebic enteritis even graver. The trichocephalus was found in about 33 per cent. and the ankylostoma in about 20 per cent.

Carriers of Dysentery Bacilli.—Flu has been unable to find records of healthy carriers of the Flexner or Y bacilli of dysentery. The carriers known to date seem to be all sufferers from chronically recurring bacillary dysentery. The Flexner bacillus seems to thrive on bile. Both this bacillus and the Y bacillus have recently been found in the general circulation in a number of cases. He queries where the dysentery bacilli remain during the latent intervals, and urges examination of the bile in all dysentery cadavers, as there is a possibility that the bacilli infest the biliary organs and may lurk here when the subject seems entirely cured. He knows of only one instance in which the bacilli were found in a cadaver with absolutely normal intestinal mucosa. They were of the Y type and were found in the bile only.

Protozoa in Human Intestine.—Flu has made a special study of this subject in the last few years, and here describes his findings. The *Ameba limax* does not seem to be pathogenic; it sometimes disappeared spontaneously from the stools without any improvement following in the clinical condition. His research on the blastocysts common in the stools examined confirmed their blastomycetic nature. But other cysts which closely resembled them proved to be forms of degeneration of tetragena cysts. His analysis of the literature and his illustrations confirm this assumption.

*Roentgen Treatment of Sarcoma. T. Eiken.—p. 1553.
Types of Tubercle Bacilli in Skin Tuberculous Lesions. C. W. Andersen.—p. 1574. Cont'n.

Roentgen Treatment of Sarcoma.—Eiken reviews the experiences at Rovsing's private clinic with roentgen treatment of sarcoma. One patient with a sarcoma originating in the diploë was given twenty-one open exposures, and the tumor which had spread to involve the dura and the cortex of the brain retrogressed completely. At present, four and one-half years after the operation, the man seems to be free from the least sign of recurrence and has full earning capacity. Eiken reviews further the publications of other Scandivanian writers on this subject; and reports a recent series of four cases. Two are in young men and the sarcoma was too far advanced for a complete cure, although benefit was derived. In all four cases the sarcoma displayed great sensitivity to the rays, and if the treatment could have been begun earlier it might have been effectual in all four cases. The third patient in the group was a boy of 7 with a sarcoma in the orbit. It was removed by Krönlein's plastic technic, without injury to the eyeball, and there has been no sign of recurrence during the two years since. He recently returned with a painful tumor in the upper arm, and roentgen treatment was promptly applied with a total of 70 H units, and normal conditions were apparently restored, except for slight changes visible only with roentgenoscopy and not palpable. The eye that had been operated on seems to be normal and the boy is otherwise strong and well. The roentgen treatment in this case had been begun two months after the first signs of the tumor. The microscope showed it to be a round cell sarcoma. The fourth patient was a woman of 31 with a cystic, painful lesion in the lowest portion of the femur. It had given trouble for seven years, and an accumulation of blood and part of one meniscus had been removed after a fall on the knee. The roentgen ray cast a shadow suspicious of sarcoma, but the long duration of the cystoma rendered this improbable. On the assumption of fibrous ostitis, the cyst was curetted and filled with 1 per cent. silver nitrate solution. The microscope then revealed that the lesion was a spindle cell sarcoma; for this the operation had been by no means radical enough. Before attempting a mutilating operation, a course of roentgen exposures was made. The condition in the knee afterward was much better than it had been for many years, and there has been no sign of recurrence or further disturbance during the eighteen months since. This combination of operation and roentgen treatment promises good results, especially when the lesion permits cross-fire exposure, as in the orbit. His case seems to confirm that the rays do not injure the eye. The boy's eye was exposed to large doses, without any appreciable by-effects. A preceding chemosis, which had followed the operation, subsided smoothly under the roentgen exposures. The reports to date on exposure of the eyeball are rather contradictory. In Gocht's case a melanosarcoma had been removed from the orbit and there had been no recurrence for nine years to date of writing.

Nirvanol. Geill.—p. 1877.
*Respiratory Exercises in Influenza. V. E. Holm.—p. 1881.
"Barbed-Wire Disease." A. Kissmeyer.—p. 1882.
*Arc Light Treatment of Laryngeal Tuberculosis. N. R. Blegvad.—p. 1910.

Deep Respiration in Influenza.—Holm noticed in his own person after an attack of bronchopneumonia that he experienced great relief after exercise in climbing that had made him pant. He then systematically practiced deep breathing exercises, and found his convalescence much hastened. He has since recommended the same to patients with acute or chronic pulmonary affections, teaching them how to breathe deep and repeat this exercise several times a day. None died in the thirty-six cases of pneumonia among his 400 influenza patients except one woman in childbirth. He would like to know if others have found respiratory exercises useful in pneumonia, etc. If so, more stress should be laid on deep respiration in treatment of pulmonary affections.

Phototherapy of Laryngeal Tuberculosis.—Blegvad gives an illustrated description of twelve cases of tuberculous lesions in the larynx in which courses of universal arc light baths were given by the technic used at the Finsen Institute. The lesions retrogressed so completely in six of the twenty-four cases that the outlook for this treatment seems very encouraging in a certain proportion of cases. In five cases no benefit was apparent, but he has not given up hope yet in all of them. (His report is in the Society Proceedings section.)

GENERALIZED INTERSTITIAL EMPHYSEMA AND SPONTANEOUS PNEUMOTHORAX

AS COMPLICATIONS OF BRONCHOPNEUMONIA

HUGH K. BERKLEY, M.D. (Los Angeles)
and
T. HOMER COFFEN, M.D. (Portland, Ore.)
Captains, M. C., U. S. Army
CAMP LEWIS, AMERICAN LAKE, WASH.

In the recent epidemic of influenza and bronchopneumonia at Camp Lewis, extensive subcutaneous and interstitial emphysema has occurred in nine patients as a complication of bronchopneumonia. The clinical picture of this emphysema, extending up over the neck, face and scalp, and down over the chest and trunk to the pelvis, and even to the external genitalia, is of such rarity and interest that the cases are here reported. Spontaneous pneumothorax has developed in two patients having extensive bronchopneumonia. That there is a relationship between these two conditions and that they are produced by similar pathologic processes has seemed likely. One case, in fact, presented, at different times, both of these complications. In this paper we are presenting an explanation of the mechanics of these unusual complications.

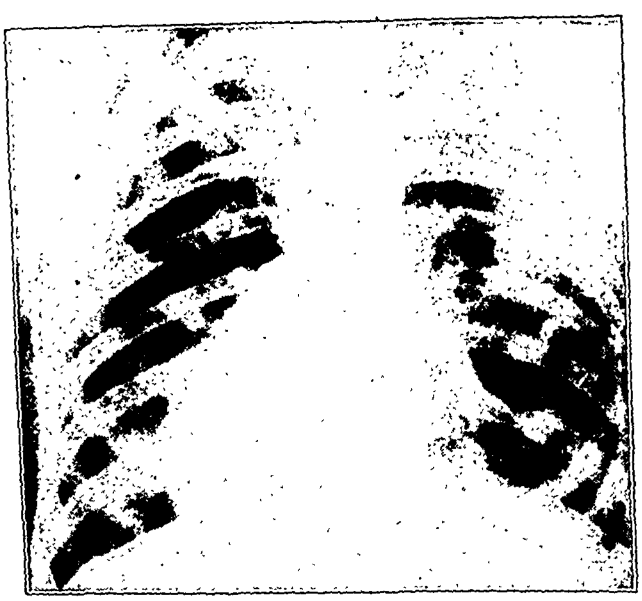

Fig. 1.—Chest in extreme generalized emphysema. Bronchopneumonia of entire right lung. Note lack of pulmonary detail due to air in subcutaneous tissues. Marked air dissection in both axillae.

In each instance, the diagnosis of our cases of bronchopneumonia has been corroborated by roentgenography, and, in fatal cases, by necropsy. Early in the epidemic it was recognized that the type of pneumonia with which we were dealing was not the type that is usually found in vigorous young adults, characterized by an acute onset with a chill followed by fever and rapid respiration. The clinical picture has, however, been one of a fairly set type. The usual onset is with general malaise over a period of from twenty-four to forty-eight hours, more or less diffuse body pains, aching joints, cough and chilliness. On admission, as a rule, the patients appeared only moderately ill. The initial temperature was rarely over 101 F. The physical signs in the lungs were often scant, so much so in some cases that they were recognized as definite pneumonias by the ward surgeons only after they had been in the hospital for from twenty-four to forty-eight hours. At this time definite lung findings were usually present, such as impaired resonance or dulness over the affected part, with either harsh or diminished breath sounds and, on inspiration, showers of fine, moist râles. A discussion of the physical signs and the diagnosis of the type of pneumonia occurring in this epidemic will be given in a subsequent paper.

After three or four days in the hospital, the greater proportion of the patients showed a marked improvement and went on to an uninterrupted recovery. In the other cases at the same time there was a tremendous extension of the process, and the condition at once became critical. It was among the latter group that the occurrence of interstitial emphysema and spontaneous pneumothorax were noted.

That our cases of pneumonia have been milder than the cases in other camps is evidenced by our mortality rate, which, at the present writing, is 9.22 per cent., or 157 deaths.

LUNG INVOLVEMENT

The patients developing emphysema or pneumothorax, for the most part, had extensive lung involvement as is shown by Table 1.

In Table 2 is shown the extent of the emphysema, together with the prominent symptoms that were apparently associated with its development. The severity of the paroxysms of cough in these cases was well demonstrated by the occurrence in one case of a rupture of the rectus muscles, and in several other cases by definite hemorrhages into these muscles. A sudden severe paroxysm of cough with pain in the chest and the spitting up of frothy, bloody sputum seemed in several cases to mark the onset of the emphysema.

Two other cases of emphysema occurred that have not been included in Table 2. One of these presented emphysema as a complication after a thoracotomy for empyema, and the other showed an emphysema following pneumothorax and thoracotomy. In both of these cases there was an extensive bronchopneumonia of the lung on the unoperated as well as on the operated side. The development of the emphysema in both of these cases, though following operation, was precisely similar to the development of the emphysema in our other cases. That there was probably *no* direct relation between the operation, per se, and the development of the emphysema will be pointed out later.

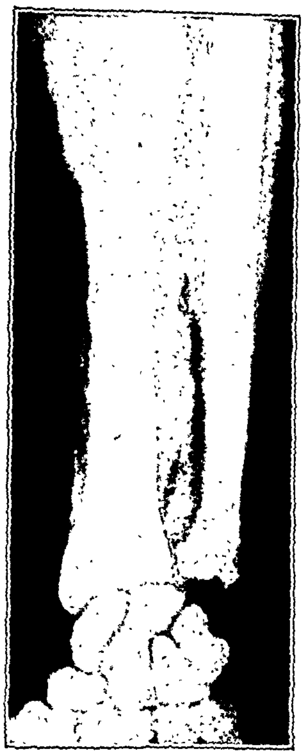

Fig. 2.—Extensive dissection of subcutaneous tissue and muscle sheaths, typical of emphysema.

BACTERIOLOGIC FINDINGS

It has been a routine in this hospital to obtain sputum cultures in all cases of pneumonia when satisfactory specimens could be obtained. Also, in case of death, cultures are taken at the time of necropsy. It has not been possible to establish any relationship between the causal organism in a case of pneumonia and the development of emphysema or pneumothorax. In Table 3 are given the bacteriologic findings in the cases reported.

ONSET AND EXTENSION OF SUBCUTANEOUS AND INTERSTITIAL EMPHYSEMA

Without exception the emphysema was first noted in the soft tissues at the episternal notch or above one or both clavicles, spreading from these points to the neck, face, scalp, chest, arms and trunk.

That this was a true subcutaneous and interstitial emphysema and not a gas bacillus infection was at once established by the absence of inflammation, by the clinical progress and by roentgenograms. In gas bacillus infection it has been clearly demonstrated by roentgenoscopy that the gas is diffusely distributed throughout the entirety of the involved tissues, whereas in emphysema the air is found to dissect its way along blood vessel and muscle sheaths in the line of least resistance. In Figures 1 and 2 are shown reproductions of the roentgenographic findings.

TABLE 1.—LUNG INVOLVEMENT IN CASES IN WHICH EMPHYSEMA OR PNEUMOTHORAX DEVELOPED

Case No.	Lobes Involved					Complication
	R. U.	R. M.	R. L.	L. U.	L. L.	
25540	+	+	+	0	+	Emphysema
27201	+	0	0	+	+	Emphysema
27365	+	+	+	+	+	Emphysema
27975	+	+	+	+	+	Emphysema
28670	+	+	+	+	+	Emphysema
29129	+	+	+	+	+	Emphysema
29292	+	+	+	+	+	Emphysema
29940	0	0	+	0	+	Emphysema
31158	+	+	+	+	+	Emphysema
24932	+	+	+	+	0	Pneumothorax
30274	T. B.	0	+	T. B.	+	Pneumothorax and emphysema

It is interesting to note that, with this extensive dissection, the patients complained of very little pain and little or no tenderness over the emphysematous areas. All patients did, however, complain of choking sensations.

MECHANISM OF THE PRODUCTION OF EMPHYSEMA AND PNEUMOTHORAX

It is of considerable interest to know just how the emphysema and pneumothorax are produced. It seems probable, as both conditions were found in the same patient at different times, that the same factors that produce one may produce the other.

TABLE 2.—EXTENT OF EMPHYSEMA, WITH PROMINENT SYMPTOMS

Case No.	Extent of Emphysematous Involvement										Symptoms at Onset	Outcome of Case
	Supraclavicular Space	Infraclavicular Space	Neck	Face	Scalp	Arms	Chest	Trunk	Genitalia	Thighs		
25540	+	+	+	+	+	+	+	+	+	+	Severe cough; bloody sputum	Recovery
27365	+	+	+	+	0	+	+	+	0	0	Choking; sharp pain in chest	Death
27975	+	+	+	+	0	0	0	0	0	0	No notes	Death
28670	+	+	0	0	0	0	+	0	0	0	Severe cough; bloody sputum	Recovery
29129	+	0	+	0	0	0	0	0	0	0	No notes	Death

29940	+	+	+	0	0	0	+	0	0	0	Severe cough; bloody sputum	Recovery
31158	+	+	+	0	0	0	+	0	0	0	Sharp pain	Death

In passing from the lungs to the chest wall the air may follow one of two routes, which may be termed (1) the intrapleural route and (2) the extrapleural route.

1. *The Intrapleural Route.*—For air to pass from the lungs to the chest wall by this route, it must pass through both the visceral and the parietal pleura. To pass through both the visceral and parietal pleura without producing a pneumothorax it must be assumed that adhesions between these membranes exist at some area and that the passage of air occurs at this point. At necropsy this seemed the possible route in but one case (27201). In this case air could be easily forced out of the lung at a point where recent adhesions had

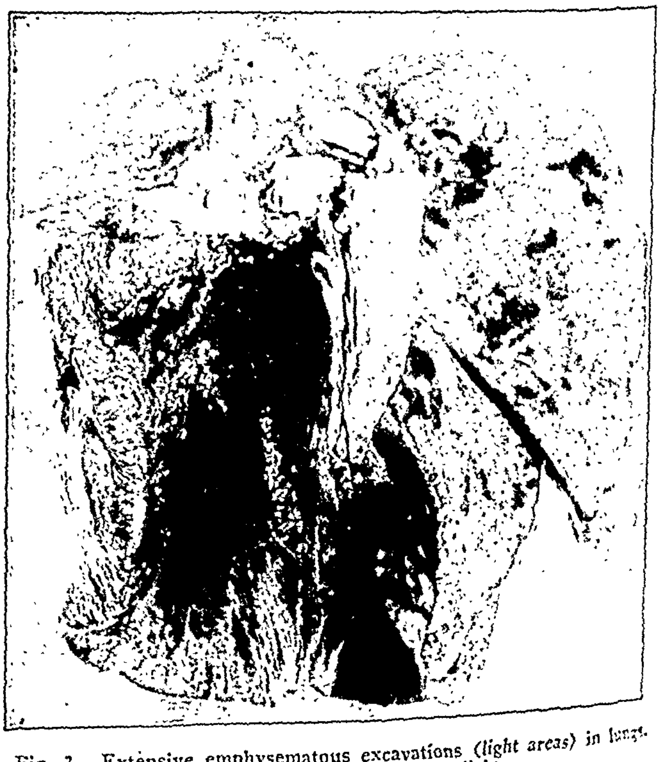

Fig. 3.—Extensive emphysematous excavations (*light areas*) in lungs. Plate taken under ray filter to eliminate *high lights*.

formed and where the parietal pleura at the corresponding point was found to be lifted up by air. It was apparently possible, in this case, to demonstrate that a direct passage of air occurred in this manner. We are of the belief, however, that this is rarely the route taken.

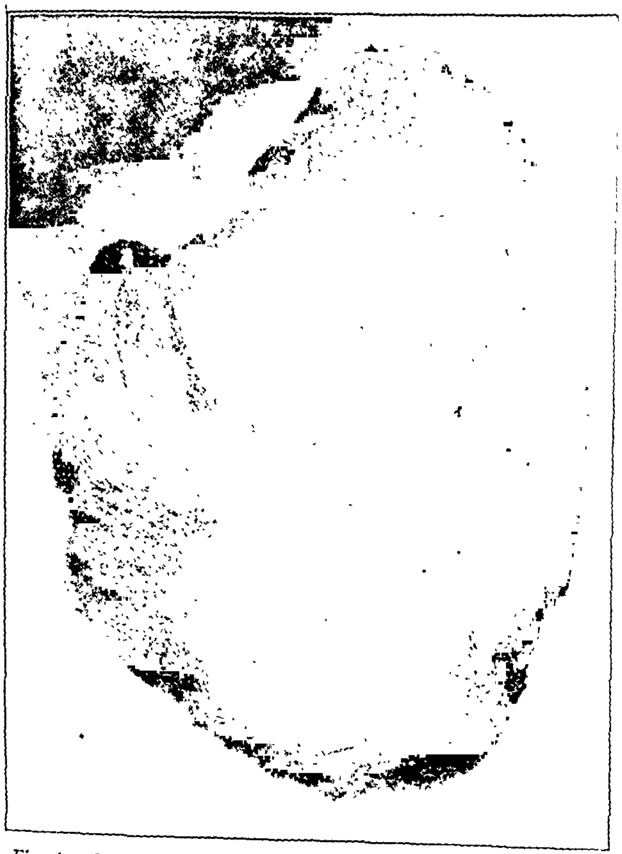

Fig. 4.—Roentgenogram of excised lung, showing well-marked emphysematous excavations especially along the lung periphery. Note especially the collapsed upper lobe and the central consolidation of lower lobe.

2. *Extrapleural Route.*—For air to gain access to the mediastinum from the lung without passing through the pleura, it would be necessary to assume a rupture of an air sac and a dissection of air from this sac back to the hilum.

TABLE 3.—BACTERIOLOGIC FINDINGS IN CASES REPORTED

Case No.	Type of Pneumococcus	Type of Streptococcus	B. Influenzae	Tubercle Bacillus
25510	IV	0	+	0
27201	0	Nonhemolytic	0	0
27363	IV	Nonhemolytic	+	0
27975	IV	Nonhemolytic	0	0
28670	IV	Nonhemolytic	0	0

29940	IV	Nonhemolytic	0	0
31158	IV	Nonhemolytic	0	0
24932	IV	0	0	0
30274	IV	0	0	+

Ruptured air sacs in the peripheral borders of the lung have been found frequently at necropsy. In many cases numerous adjacent air sacs have ruptured, forming a large air space, aptly termed "emphysematous excavations" by our roentgenographer, Capt. F. E. Diemer. On removal of the lungs, these excavated areas were found to be distended and covered by tense pleura. Leading off from these excavations were "air streaks" (a term suggested by Capt. M. C. Terry), definitely following the course of blood vessels. Air could be readily forced from the air spaces to the air streaks.

Dissection of the lung also showed that these air streaks could be traced along the course of blood vessels to the hilum. Also, by exposing the hilum of the lung extrapleurally without rupturing the bronchus, and submerging it in water, it was possible, by gently squeezing the lung, to force bubbles of air out at the hilum, the bubbles rising from around the blood vessel walls. This was accomplished through the mediastinum, with the lungs still in place in the chest cavity. Thus it is seen that, with a valvelike entrance from a bronchiole into an air space, a continual flow of air will be produced from the parenchyma of the lung to the soft tissues of the posterior mediastinum. From the posterior mediastinum the air dissects its way to the superior mediastinum, and enters the subcutaneous tissues of the neck and axilla by following the blood vessel sheaths through the deep fascia.

Many cases that did not show a pneumothorax or an emphysema of the chest wall were found at necropsy to have numerous excavations of varying size. They were so extensive in some instances that the lingula or the entire anterior margin of the lobes appeared to be blown up with air. A photograph of one of these lungs is reproduced in Figure 3. Also, by taking roentgenograms of the lung after removal it was possible to show these areas fairly well. A reproduction of one of these plates is given in Figure 4. This is contrasted in Figure 5 with a similar roentgenogram of an ordinary emphysematous lung.

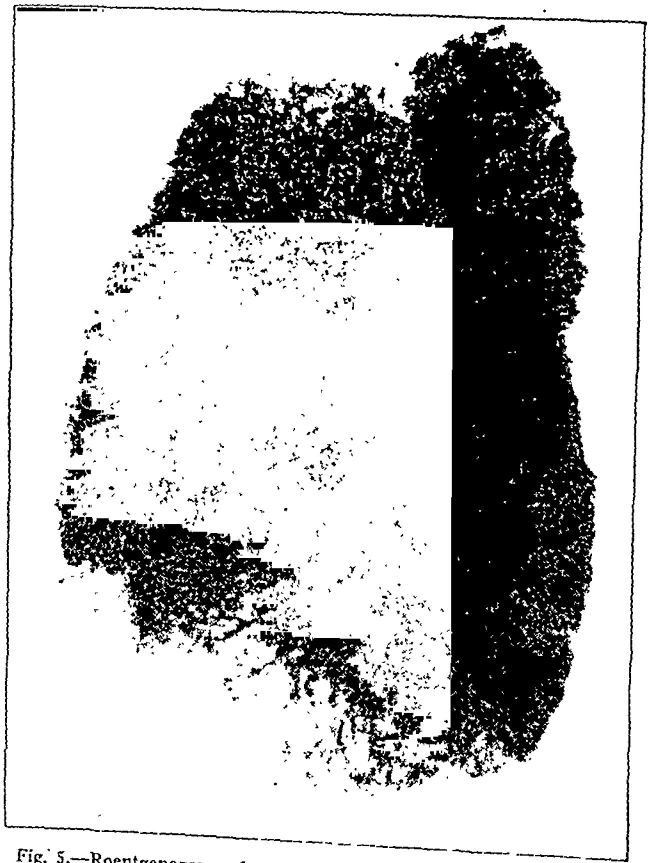

Fig. 5.—Roentgenogram of an excised lung, showing a true pulmonary emphysema without emphysematous excavations. Compare with Figure 4.

It was also possible, by roentgenograms, to show excavated areas in certain of the more marked cases during the life of the patient (Fig. 6). The future of these patients, showing emphysematous excavations, who eventually recovered from their pneumonic infection, presents an interesting problem. One patient, now quite convalescent, still shows these areas by roentgenoscopy. Whether they will eventually contract down and close by scar tissue formation, or will develop into bronchiectatic cavities, only time will tell.

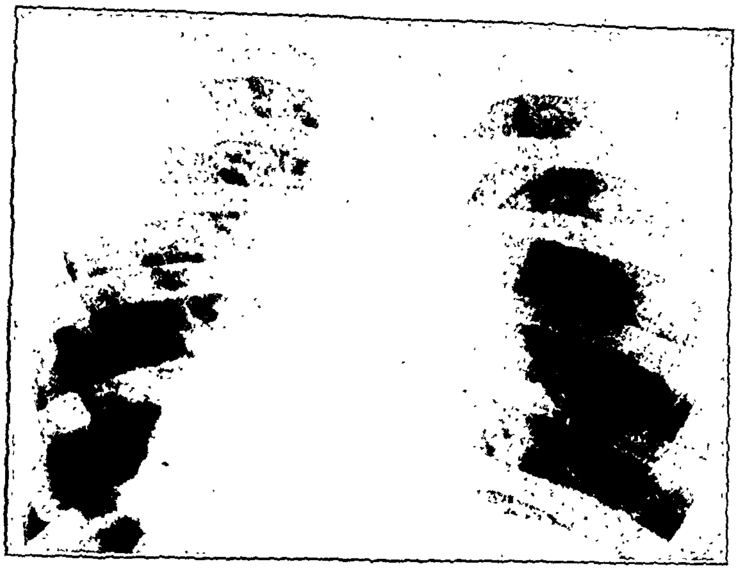

Fig. 6.—Roentgenogram in a case of bronchopneumonia (resolved, both bases), showing an emphysematous streak along the course of a blood vessel in midportion of right lung field.

PNEUMOTHORAX

As stated above, it seemed likely that the same process that resulted in emphysema in one case might in another result in a pneumothorax. With the formation of the emphysematous excavations on the peripheral border of the lungs, the pleural covering was lifted and put under considerable tension. From these points the dissection of air toward the hilum took place. In paroxysms of coughing the pressure within this space was, of course, considerably increased. Any obstruction to the dissection of this air along the vessel sheaths, or an increase in pressure that exceeded the rate of outlet by dissection, would result in a rupture of the pleural covering of this air space, and a pneumothorax would result. This condition occurred in two of our cases. The roentgenograms of these cases are given in Figures 7 and 8. The pressure fluid present in both of these cases may possibly have been the reason for the delayed escape of air from the air spaces by dissection along the vessel sheaths. In Case 30274, however, tuberculosis must be borne in mind as a possible cause for the pneumothorax.

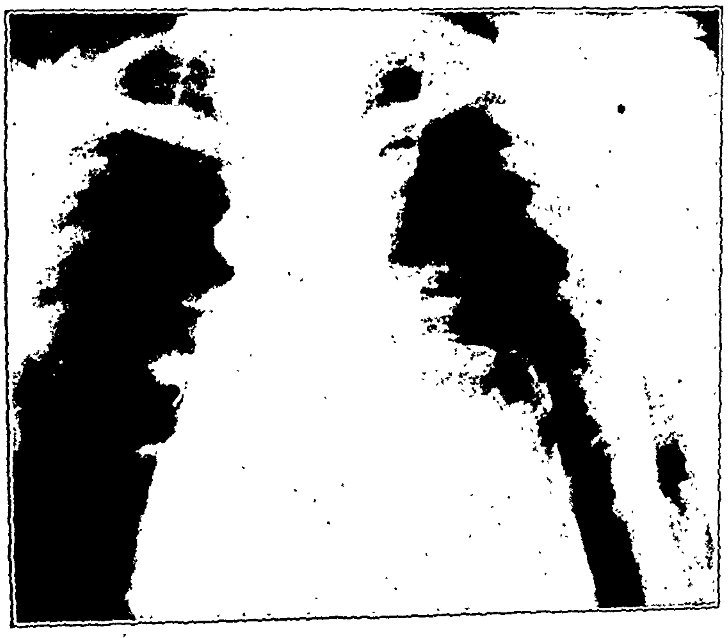

Fig. 7.—Roentgenogram in case of pneumothorax after thoracotomy for relief of pressure. By fluoroscopy prior to thoracotomy the right lung was markedly compressed and the heart pushed to the left. The lung is in the position of collapse and the heart is not displaced.

The symptoms in the two cases of pneumothorax varied widely. Patient 24932, coughed frothy, bloody sputum for three or four days, but showed little or no discomfort, while Patient 30274 was extremely dyspneic. To relieve this dyspnea a thoracotomy was done. Stereoscopic examination in this case prior to thoracotomy showed the right lung to be markedly compressed and the heart forced markedly to the left. After thoracotomy the lung expanded to the position of collapse and the heart returned to its normal position (Fig. 7). Six hours after the thoracotomy a well-marked emphysema was found in the suprasternal notch and above the clavicle on the right side, although careful search revealed no emphysema around the operative wound. It is believed that the marked pressure of the pneumothorax on the hilum prevented the exit of air from the hilum of the left lung, and that the release of this pressure by thoracotomy allowed its escape into the mediastinum with the resultant emphysema.

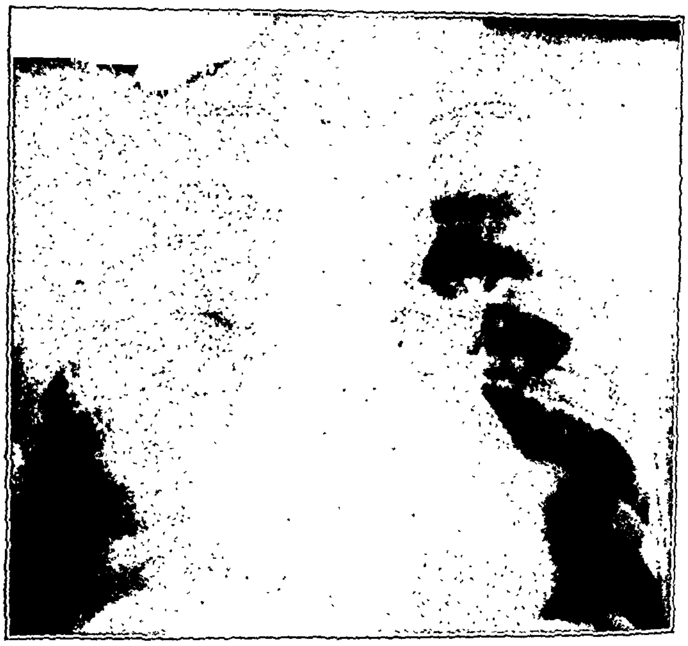

Fig. 8.—Pyopneumothorax. Exposure made with patient in prone, postero-anterior position. The decrease in radiability over the pneumothorax is due to the fluid present. The right upper lobe is not collapsed, owing to the well-marked pleural adhesions. Note the heart displacement and lung compression due to pressure of the pneumothorax.

A similar explanation is offered for the development of the emphysema, postoperatively, in Case 27201 (Fig. 9). It is assumed that the fluid in the left chest caused a compression of the hilum, thus preventing the escape of air until thoracotomy had been done. The emphysema first developed on the side opposite to the operative wound, and no emphysema was noted about the wound. It was on the unoperated side in this case that it was apparently possible to show the direct passage of air through pleural adhesions to the chest wall.

COMMENT

The rarity of the two unusual complications of bronchopneumonia described in the foregoing is emphasized by their occurrence in only eleven out of 1,701 cases of bronchopneumonia seen at this hospital during the recent epidemic.

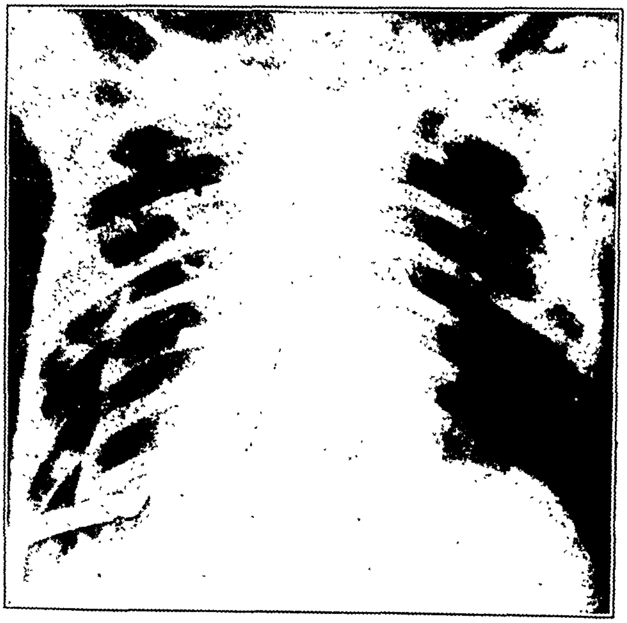

Fig. 9.—Extensive emphysema developing after thoracotomy for empyema. Note equal air dissection in both axillae. Clinically the emphysema was first noted above the right clavicle (operation on left side). No emphysema around operative wound. Pneumonic process not visible, owing to the marked emphysema.

PREVENTION OF RELAPSES IN CASES OF ARRESTED TUBERCULOSIS AMONG SOLDIERS [*]

S. ADOLPHUS KNOPF, M.D.
Professor of Medicine, Department of Phthisiotherapy, New York Post-Graduate Medical School and Hospital
NEW YORK

Relapses from tuberculosis in the civilian population, particularly among the working classes, present a most difficult medical and economic problem; but when we are dealing with soldiers and sailors, that is to say, young men between the ages of 20 and 36, representing the flower of the manhood of the nation, it becomes all the more serious. In my address on "Blinded Soldiers as Masseurs," read before the Conference on Rehabilitation of the Wounded in Philadelphia, Sept. 20, 1918, I[1] endeavored to throw out some suggestions as to the possible solution of the study of the various phases involved and a description of some therapeutic methods whereby it is hoped to reduce the number of relapses among tuberculous soldiers and sailors and, if possible, to shorten the time necessary to attain a reasonable security against any recurrence of the old trouble, thus aiding an early and permanent rehabilitation.

Not only we so-called tuberculosis specialists, consultants or sanatorium physicians in civil practice, but also that splendid corps of men and women who are our collaborators in solving the social problems of tuberculosis, know of the frequency of relapses among those who are sent home from the sanatoriums or health resorts as arrested or apparently arrested cases. However, it is not the fault of the sanatorium physicians or practitioners in climatic health resorts that in many cases which have been discharged as arrested, relapse occurs sooner or later and sometimes after relatively short periods. The vast majority of our tuberculous patients leave our sanatoriums and resorts too soon because of economic necessity and their eagerness to return home in order to make a living for themselves or their dependents. I am sure that if it were in the power of the sanatorium authorities or practitioners in the health resorts to retain them longer, many relapses would be avoided.

The patients that are discharged or discharge themselves as arrested or nearly arrested cases, are not considered even "apparent" cures. The definition of the term "apparent cure" is that all constitutional symptoms and expectoration with bacilli shall have been absent for a period of at least two years under ordinary conditions of life. An arrested case is one in which all constitutional symptoms, expectoration and the bacilli have been absent for a period of six months, and the physical signs are those of a healed lesion. An apparently arrested case is one in which all constitutional symptoms and expectoration with bacilli have been absent for three months, the physical signs being those of a healed lesion.

For a long time I have asked myself, What can and should be done in order to shorten the period between the time when a case is arrested and when it can be considered cured? I have already absolved the sanatorium and health resort physicians from blame, but there is no denying the fact that a great number of patients return home, with the label "arrested case," whose muscles are flabby from the prolonged rest-cure on the

[*] Read before the North Atlantic Tuberculosis Conference, Pittsburgh, Dec. 7, 1918; before the Clinical Society of the New York Post-Graduate School, Jan. 17, 1919, and before the Section on Medicine of the New York Academy of Medicine, Feb. 18, 1919.

[1] Knopf, S. A.: Med. Rec. 94:709 (Oct. 26) 1918.

reclining chair, whose respiratory systems have become indolent because they could not and should not breathe deeply while their lesions were active. Very often the excellent climatic conditions that prevail in sanatoriums and health resorts have tended to increase the patient's sensitiveness to atmospheric changes, and not to heighten his resistance to the invasion of pneumococci and the minor respiratory infections, all of which tend to reawaken an arrested tuberculous lesion. Add to these the disturbing factors of the toxins (fatigue poisons) produced by overworked flabby muscles, and we need not wonder at the frequent relapses.

In some institutions hydrotherapy is employed, and this is after all our best means to fortify the circulatory, cutaneous and nervous systems against atmospheric changes and the invasion of micro-organisms through our respiratory systems; but in many sanatoriums nothing is thought of the value of the external use of cold water as a tonic to render the system immune, as far as it is possible, to so-called colds. In my humble opinion, hydrotherapy is a most important therapeutic agent in the treatment of tuberculosis, particularly during the period of convalescence after the arrest of the disease.

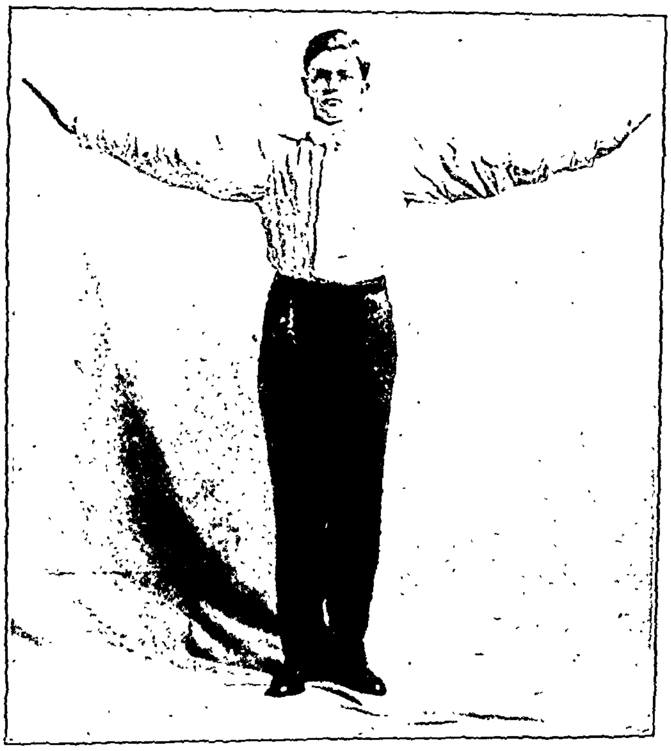

Fig. 3 (second exercise).—Arms horizontal.

VALUE OF MASSAGE

The same things may be said regarding that important part of our armamentarium for the treatment of numerous diseases in modern as well as in ancient medicine, known as massage, so sadly neglected by most of us in the management of tuberculous cases.

In my hospital practice in the city of New York, where I have to deal almost exclusively with advanced cases of tuberculosis, it is obvious that the application of massage is not feasible and but rarely indicated; the same holds good of routine hydrotherapy or respiratory exercises. But in private practice I have found massotherapy, hydrotherapy and respiratory therapy of the greatest value for convalescent patients and those returned from the sanatorium as arrested cases. During my student days in this country and abroad, it was my good fortune to have had opportunity to study massage and what is known as the Swedish movement cure. I have taught these valuable therapeutic adjuvants to many of my pupils and nurses; and in cases in which, for financial reasons, a professional masseur could not be employed, I have often succeeded in teaching a well member of the family how to apply the treatment to the tuberculous invalid. It was surprising to me to see how many men and women there are with a natural aptitude for this work. In some instances they developed into experts so that I could employ them advantageously in other families.

Because of the skill acquired by some of my assistants, nurses, and friends of patients and their willingness to apply massage to that class of invalids, I believe I have had considerable success in guarding arrested cases from relapses and in preparing them for more active physical exercise and work, particularly when hydrotherapy and carefully graded respiratory exercises could be added to the massotherapy. After all, we must admit that in spite of our advance in serology and immunology, we have up to this date no medicinal agent or culture product that will protect the arrested case against a recurrence of the disease. Physiotherapy, that is to say, a judicious combination and application of massage, cold water, and graded breathing exercises, seems, up to this date, our only means to prevent relapses in arrested cases of pulmonary tuberculosis. It should be applied for a period of from four to six weeks after the case has been pronounced arrested. Individualizing in the postsanatorium treatment is as essential as in the sanatorium treatment proper. It is evident that such patients must also be taught that prudence, temperance and a hygienic mode of life must be the rule for their conduct ever after, if they do not wish to undo the good effects of the sanatorium and postsanatorium treatment.

Such postsanatorium treatment is not in any way intended to do away with the contemplated program of teaching our tuberculous soldiers a variety of trades and occupations before they leave the military hospitals, each occupation adapted to the individual so that it will be most conducive to the preservation of his health and helpful in reestablishing his earning capacity.

It was more than gratifying to me to learn from my esteemed teacher and friend, Prof. Hermann M. Biggs, whose many years' experience with work-therapy at the Otisville Sanatorium entitles him to express an authoritative opinion, that he agrees with me as to the value of combining the three important adjuvants in phthisiotherapy to prevent relapses. In a letter to me he writes:

> In my opinion, massage, graded respiratory exercises, and hydrotherapy judiciously applied are often of great service in the treatment of arrested cases of pulmonary tuberculosis.

In connection with this endorsement of the value of massage, may I call attention to the fact that all the objections that confront us in applying massage in private practice, in sanatoriums or in civil hospitals, such as financial considerations, unwillingness of the patient to remain, scarcity of masseurs, or phthisiophobia on the part of the latter, need not enter into consideration when we deal with our war heroes, the tuberculous soldiers.

I have the assurance that a number of war blinded soldiers will be trained as masseurs in U. S. Base Hospital No. 7 for the Blind at Roland Park, Baltimore, which is under the able direction of Lieut.-Col. James Bordley. If this hospital should not be able to provide a sufficient number of masseurs for our tuberculosis work, there will be among our maimed heroes a number who have received injuries to the lower extremities and other types which might be found who could be trained as masseurs. Any unwillingness to remain under medical supervision, when as complete a recovery as can be expected is not attained, is met by the bulletin issued by the Surgeon-General, which reads: "Hereafter no member of the military service disabled in line of duty, even though not expected to return to duty, will be discharged from service until he has attained complete recovery, or as complete recovery as it is to be expected that he will attain when the nature of his disability is considered." Phthisiophobia in the blind need not be feared, nor in any other one-time soldier who has learned to obey and who will believe his officers when they assure him that the contact with a clean, conscientious tuberculous patient, particularly an arrested case that has had sanatorium training, cannot be in the least dangerous to a masseur. The matter of expense to the government which the employment of a number of masseurs would entail in the rehabilitation of the tuberculous soldier and making him a bread winner again, able to support himself and his family and become a useful citizen, is, of course, something that can be considered only as an ultimate advantage. Economy in such matters as these is unworthy of a great country such as ours, a generous republic willing to do all it can do for its soldier citizens who have fought and suffered for their country's and humanity's sake.

This paper would be incomplete were I not to describe massage, the method of applying hydrotherapy, and the graded respiratory exercises indicated in cases of arrested pulmonary tuberculosis.

CHARACTER OF MASSAGE INDICATED IN ARRESTED TUBERCULOSIS

The room in which the patient is to be massaged should be comfortably warm and always well ventilated. To avoid unnecessary exposure it is well to have handy, besides the ordinary bed covering, a shawl or small blanket to protect the parts of the body that are not manipulated at the time. Whether or not to use white petrolatum or talcum powder for the purpose of lubrication will depend largely on the skin conditions of the masseur or patient. As a rule, lubricants are not necessary. The patient should be placed on a moderately high table, or bed with no springs. The height of the bed or table should be suited to the height of the operator. The latter must be able to bend over the patient comfortably and to exert a moderate amount of force without getting too tired himself. A low bed with a spring cannot be used for applying massage scientifically.

The classical books on massage teach a variety of movements, such as effleurage (stroking), friction, pétrissage, vibration and tapotement (hacking). I believe that for the average convalescent or arrested tuberculous case in which general massage is indicated, the following simple movements suffice for all practical purposes: namely, friction, kneading, tapping and stroking. In the friction movement of the extremities, and as much as possible in all the others, the course of the venous circulation should be followed, and in abdominal massage one must have in mind the situation of the small intestine and the colon, so as to aid in overcoming a tendency to constipation. This is done by making a circular motion around the umbilicus from right to left. The colon should be manipulated separately, following its course along the ascending, transverse and descending portions. This massage of the abdominal wall, particularly when there is little adipose tissue, should be more gentle than that of any other portion of the body, and should be supplemented by teaching the patient to retract and relax the diaphragm alternately, holding it for several seconds in the retracted position so as to strengthen all the abdominal muscles.

Of course the massage of no matter what organ should be done with the patient in a recumbent position and in complete muscular relaxation. In giving a general massage it is always best to begin with the lower extremities, starting with the toes from joint to joint, and next to take the plantar and dorsal surface of the foot, from toes to ankle joint, then upward from ankle to knee joint, from knee to hip, and then the abdomen in the manner already described. Next in order are the head and neck, in which the manipulator must, of course, be more gentle than over the extremities. The hands, arms, forearms and thorax are manipulated in the order mentioned. Each finger is frictioned as far as the wrist articulation, then the arm from there to the elbow, and from the elbow to the shoulder. By a semicircular movement, with the palms of the hands and moderately spread fingers, one takes in by the friction movement as much as possible of the posterior and lateral portion of the thorax.

The friction from one joint to another should be applied about four times before beginning with the kneading, which method is explained by the name itself. One manipulates the muscles so as to lift them from the osseous attachment and in the same order as the friction movement. The third movement is the tapping, which may be done with the whole hand, the palmar surface of the four fingers, or if desirable to avoid the clapping sound produced by this movement, one may tap with the ulnar surface of the hand, producing a sort of chopping movement.

The stroking or soothing movement (effleurage) is the last of the four, and consists in gently passing over the entire surface of the body, encircling the extremities with one hand, or both hands, making the strokes over broad surfaces with the flat hand. A fifth movement consists of pinching the skin for the purpose of exciting the circulation and innervation of inert skin. This form of massaging the cutaneous surface must be done rapidly, at least at the rate of 100 a minute. One should grasp a fold of the skin and not relax it until it is seized by the finger and thumb of the other hand. This fifth movement is indicated in only a relatively small number of cases of arrested tuberculosis; but when it is used it should be followed by the effleurage. This stroking movement should always be the last.

The patient is now turned on his chest with either the right or left cheek resting on a small pillow so that he can breathe easily during the manipulation of the posterior muscles of the lower extremities, the thorax, arms, forearms, etc., in the same order as the anterior portion. If the masseur is tall and vigorous and the patient not larger than he, it is possible to apply the friction movement to both arms, both shoulders, and right and left portion of the thorax at the same time. This is done by placing the palms of the hands on the posterior portion of the patient's hands and making a good friction movement over the hands, forearms, arms, shoulders and the posterior portion of the patient's thorax.

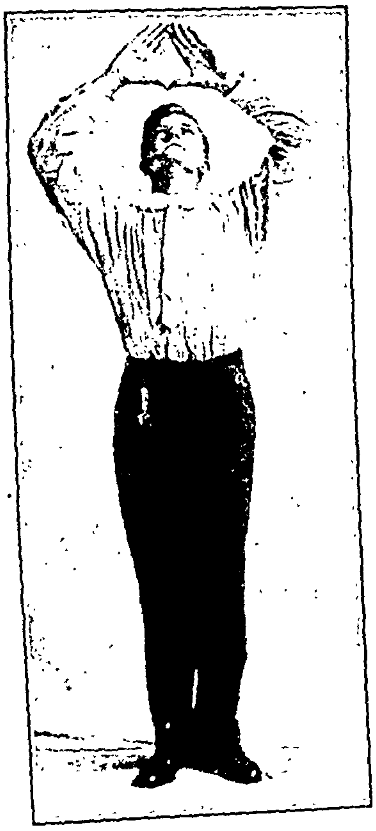

Fig. 6 (fourth exercise).—Arms above head.

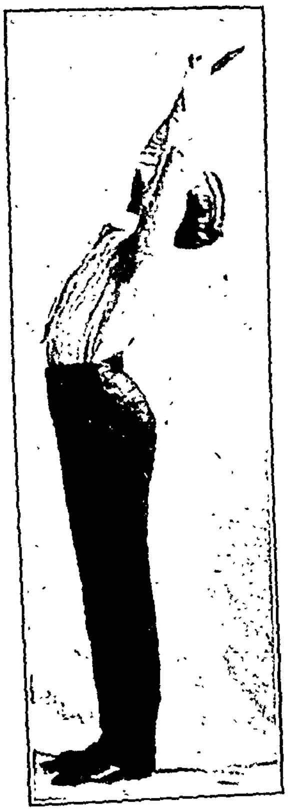

Fig. 7 (fourth exercise).—Bending backward.

The kneading, tapping and stroking movements will remain the same as for the anterior portion, with the only difference that the buttock and the posterior muscles of the trunk will stand a more vigorous massage than the anterior ones. Just as in friction, one should apply kneading, tapping and pinching not more than four times to each portion of the body, so that the time occupied for the entire massage of the body, anteriorly and posteriorly, should not exceed forty-five minutes. It is immaterial at what time the massage is given to the patient, as long as about one and a half or two hours have elapsed after the principal meals.

The so-called movement cure can, of course, be added to this general massage, and it is not difficult to teach or to apply. In applying it one must bear in mind the physiology of the joints and their natural limits of motion. These joint manipulations consist in assistive, passive and resistive movements of the extremities. Although helpful, they are hardly necessary in the average case of the recovered tuberculous invalid. They are often resorted to in certain nervous and rheumatic affections, especially in surgical and orthopedic practice, and should always be done under the guidance of the physician or surgeon in charge of the case.

Assuming that the arrested case of tuberculosis might be looked on as fairly sound physiologically, what, may we ask, is the effect of massage on the circulation, for example. "It rouses dormant capillaries, increases the area and speed of the circulation, furthers absorption, and stimulates the vasomotor nerves, all of which are aids and not hindrances to the heart's action and to nutrition in general."[2] Of course, massage cannot manufacture blood cells or coloring matter, but it can put in circulation those that are dormant in the system. Unless this is done there results the condition picturesquely described by the poet physician, the late S. Weir Mitchell, as "like the want of circulating money during times of panic, when gold is hoarded and not made use of, and interference with commerce and manufacturing results." Thus we find that the anemia, so often still persistent in the apparently arrested case, may be successfully combated by massage. I have already referred to the beneficial effect of massage on the flabby disused muscles.

METHOD OF APPLYING HYDROTHERAPY

We now come to the next most important measure in physiotherapy for the rehabilitation of tuberculous soldiers, namely, hydrotherapy. In applying any hydrotherapeutic measure to the arrested tuberculous case one must ascertain first whether or not the patient has been using cold water during his convalescent stage as an ablution, shower bath or dip, or in any other form, and at what temperature. Supposing the individual has never used cold water on his body, what are we to do in order to train him and be sure of reaction, and what is the simplest apparatus necessary so that this hydrotherapy can be applied anywhere?

The important precaution to be taken in such cases is not to chill the patient. As a beginning, the cold water application should be made in the form of an ablution, either in the morning when the patient arises from his bed, or in the evening after he has been in bed for about ten minutes and has become thoroughly warm. If necessary the bed can be warmed with the aid of a hot water bag, which may remain at the feet of the patient. It is also well to have the hydrotherapeutic arrangement as near the bed as possible. To this end one should use a circular English bath tub, about 3 feet in diameter and 10 inches high, and pour about 5 inches of water into it at about 105 F. The second part of this simple hydrotherapeutic arrangement consists of a wash basin full of cold water with a large sponge, placed near the larger basin on a table of ordinary height. The temperature of the cold water can vary from 40 to 85 F. From 40 to 45 is usually the temperature of the water coming out of the faucet. It is best to begin with the cold water at a temperature of 85 and then go down gradually 5 degrees every four or five days until a temperature of 40 is reached and borne comfortably. It is always well to have the windows closed and the room warmed while the patient is taking his cold water application. If in spite of all these precautions the patient should fail to react, the cold baths must be discontinued.

---

[2] Graham, Douglas: Massage, Manual Treatment, Remedial Movements, Ed. 4, Philadelphia, J. B. Lippincott Company, 1913.

The ablution is applied in the following way:

At the beginning the orderly in attendance, and later on the patient himself, takes the sponge soaked in the cold water while the patient stands in the hot water, and squeezes out the sponge first over the back of the neck, then in front, over the thyroid, then over his left shoulder, and then over the right, so that the entire body has been bathed with cold water. The patient then dries himself quickly, not necessarily very thoroughly, with the aid of a large, rough towel, and returns *immediately* to the bed. Under the warm cover he will feel warm and the little moisture left on his body will soon dry. Through this procedure reaction is assured, and the patient rarely fails to feel comfortable and enjoy the cold water application. If the head should get wet accidentally, he should dry it thoroughly. This is a precaution the patient should always take whenever he has washed his head.

When the system has become accustomed to the water used in this way, the patient can safely resort to the application of a needle or shower bath, or can take a dip into the water as cold as it comes out of the faucet, provided he reacts favorably.

I have made extensive use of hydrotherapy with most gratifying results, and became enthusiastic concerning its beneficial effects in phthisiotherapy in my early career as assistant to Dettweiler in the Falkenstein Sanatorium. In speaking of and recommending hydrotherapy, I always like to insist that the plentiful ingestion of pure water, in preference to all other beverages, plays an important part in the success obtained with the external application of cold water.

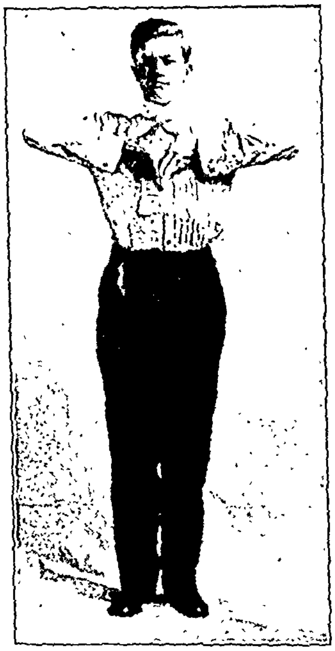

Fig. 9 (fifth exercise.)—Hands upward from abdominal position.

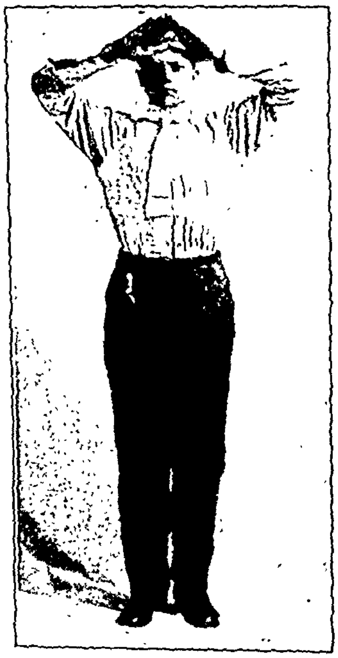

Fig. 10 (fifth exercise.)—Hands raised from chest and *turned*.

GRADED RESPIRATORY EXERCISES

Respiratory exercises should not be resorted to as long as there is activity in the chest. But since we are dealing only with nearly or entirely arrested cases in which all symptoms have disappeared, we need not fear any harmful effects from this part of our physiotherapy. Nevertheless, as will be seen, breathing exercises should be graded and the chest not violently but gradually expanded. The simplest of all exercises, one that can be taken even in bed or sitting on a chair, in a carriage or automobile, also without attracting the least attention while walking outdoors, since it requires no motion of arms, is as follows:

Raise the shoulders (Exercise A, Fig. 2), making a rotary backward movement during the act of inhaling; remain in this position holding the breath for four seconds, and then exhale while moving the shoulders forward and downward, assuming again the normal position (Fig. 1). When Exercise A is thoroughly mastered, begin with the following: In front of the open window or outdoors assume the position of the military "attention," heels together, body erect, and hands on the sides (Exercise B, Fig. 1). With the mouth closed take a deep inspiration (that is to say, breathe in all the air possible), and while doing so raise the arms to a horizontal position (Fig. 3), remain thus holding the air inhaled for from four to five seconds, and while exhaling bring the arms down to the original position (Fig. 1). The act of exhaling, or expiration, should be a little more rapid than the act of inspiration.

The act of inhalation occupies about four seconds, the act of exhalation about three seconds, and as has already been said, the act of retention of the air about five seconds. One counts mentally during these three acts so as to be systematic about holding the air. The hands may be moved upward and downward twice counting four, and on the fifth second one begins to exhale while lowering the arms.

When the second exercise (B) is thoroughly mastered, the third one (C) may be begun. Place the arms, one above the other, in front of the chest giving the hands the position as though wanting to tear the chest open (Fig. 4). Hands, arms and shoulders then make a backward movement (the fingers remaining bent) while a deep inhalation is taken. Count four by tapping the chest four times with both hands (Fig. 5) and at the fifth second start to exhale, bringing the hands and forearms into the position from which they started (Fig. 4). This exercise has the advantage that it can be taken in the sitting position or even when lying on the back.

The fourth exercise (D) consists in raising the arms from the sides (Fig. 1) to the horizontal (Fig. 3) and then above the head (Fig. 6), taking a deep inhalation during this act; then bending backward (Fig. 7) as far as possible and remaining in that position four seconds while retaining the air (counting the seconds by moving the hands alternately forward and backward twice) and on the fifth second exhaling gradually while resuming the original positions (Figs. 3 and 1). During this exercise when the arms are raised until the hands join, do not bring the arms close to the head, but form a sort of circle above the head by bending the elbows outward far enough so that the meeting of the index fingers and thumbs forms a triangle (Fig. 6).

The fifth exercise (E) is for the purpose of bringing the abdominal muscles also into play, or in other words, for combining abdominal and chest breathing. To this end assume an erect position, as in the beginning of all the exercises, let the hands meet in front with the little fingers and the edge of the palms touching the abdominal muscles (Fig. 8). While taking a deep inspiration raise the diaphragm, concentrating all attention on this act, and while doing so move the joined hands upward, sliding them along the thorax (Fig. 9) up to the chin. Next turn the hands (Fig. 10) and continue to raise them until they are above the head (Fig. 6); bend backward (Fig. 7) during the four seconds while retaining the air and then exhale, lowering the arms gradually to the horizontal (Fig. 3) and then to the original position of "attention" (Fig. 1).

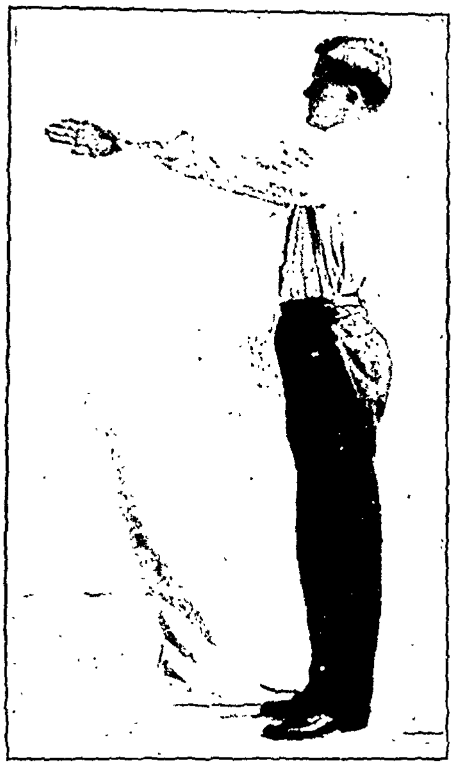

Fig. 11 (sixth exercise.)—Arms as in swimming.

The sixth breathing or respiratory exercise (F), which may also be called a dry swim, requires more strength and *endurance*. It should not be undertaken until the others have been practiced regularly several times a day for a few weeks, and until an evident improvement in breathing and general well-being has been observed. Take the usual position of military "attention" and then stretch the arms out as if in the act of swimming (Fig. 11), the backs of the hands touching each other. During the inspiration move the arms outward (Fig. 12) until they finally meet behind the back (Fig. 13). Remain in this position for the usual four seconds, counting by moving the hands while retaining the air, and on the fifth exhale, bringing the arms forward again (Fig. 14), ready to start for another swim (Fig. 11); or if this is the end of the dry swim, the arms return to the original position of "attention" (Fig. 1).

This somewhat difficult exercise can be facilitated and made more effective by rising on the toes during the act of inhalation (Fig. 12) and descending during the act of exhalation.

It will be seen that with the aid of these six respiratory exercises every muscle of the body is put into play. The face alone is at rest and can serve as an indicator that the exercises are properly done, for it should be borne in mind that they must be taken without any undue tension of the muscular system, and tremor-like movements must be avoided.

The following general rule concerning breathing exercises should always be remembered: Commence with the easier exercises (A) and do not go on with the more difficult ones until the former are completely mastered. Take from four to six respiratory exercises at a time, one of each, or when outdoors simply the first exercise, from four to six times every half-hour or hour, or at least four to six times a day and on rising in the morning and on retiring at night. Continue this practice until deep breathing has become a natural habit. These exercises should always be taken in an atmosphere as fresh and as free from dust as possible. Never take these breathing exercises when tired, and never continue so long as to become overtired. I repeat once more the important injunction that the muscles of arm and forearm, or any of the other muscles coming into play during the respiratory exercises, should never be on a tension but rather relaxed, so as to avoid the expenditure of unnecessary muscular energy.

Besides the exercises described above there is one more that after having learned all the other movements the recovered tuberculous soldier or sailor can add as a means to develop his chest by taking in the greatest possible amount of pure, fresh air. To this end he should proceed as follows:

> Take the usual position of "attention" (Fig. 1), then inhale deeply, *rolling* the shoulders upward and backward, holding the air for four seconds (Fig. 2), and on the fifth second exhale all the air possible. Assume again the original position (Fig. 1); but before inhaling again, make a second expiratory effort while turning the arms outward (movement of supination) and pressing the inner side of the upper arm against the chest (Fig. 15), and thus, so to speak, squeezing out all the air there is left in the lungs. An emptiness in the lungs is created in this way and the patient involuntarily takes a very deep inhalation (Fig. 16), after that assuming the ordinary quiet position of "attention" (Fig. 1).

With the aid of all these exercises we bring about an increase in hematosis. From our physiologic studies we recall that during ordinary inhalation and exhalation the amount of tidal air inhaled is only 500 c.c. The volume that can be inhaled by the first exercise is 1,500 c.c., known as complemental air, and the volume that can be exhaled by this exercise—supplemental air—is about 1,300 c.c. When now the second expiratory effort is added, aided by the supination of the arms and pressure against the chest, 500 c.c. more of reserve or residual air can be expelled. It is evident that this last exercise tends to enhance the value of respiratory therapy.

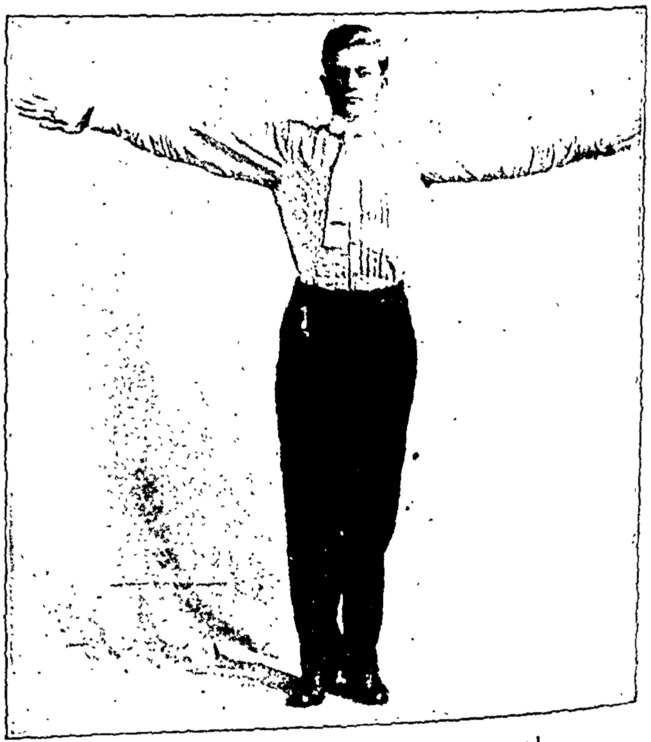

Fig. 12 (sixth exercise).—Arms moved outward.

CHOICE OF OCCUPATION

When all three of the measures just described—massotherapy, hydrotherapy and respiratory therapy—have been applied for a number of weeks and the patient is considered as safe against any relapse as the physician's skill and his own personal training and care can make him, there remains the necessity of selecting an occupation and environments for him that will tend to increase his chance of remaining well. This is a problem in itself, and all I can say here is that in a general way the more the individuals who have passed through *postsanatorium* treatment can be occupied outdoors, the less danger will there be of any renewal of the disease. At the same time we must bear in mind that there will be many who are neither temperamentally disposed nor physically fit to do agricultural or horticultural work, to raise chickens, drive trucks, become chauffeurs or outdoor salesmen, or be ticket choppers on elevated railroads. For those who have had the necessary training and are willing to occupy such or similar positions, which will assure outdoor life and at the same time enable them to make a comfortable living, nothing better could be selected. But there will be many men who, prior to entering the Army, had been successful in pursuing trades or professions which demanded indoor life, for which they had been prepared by years of training and study and in which they made a very comfortable living. Such would wish, if at all possible, to return to their former field of labor, and I am inclined to believe this can be done safely in many instances, provided the indoor office or workshop is sanitarily constructed and well ventilated, and that the individual lives the most hygienic life possible at home. It is especially important for him to sleep in a well ventilated room. The windows should be wide open, and whenever it is possible, he should sleep outdoors on the porch, in a tent placed on the roof, in the garden or yard. For those living in city apartments or tenement houses, I would suggest the installation of the indoor window-tent.

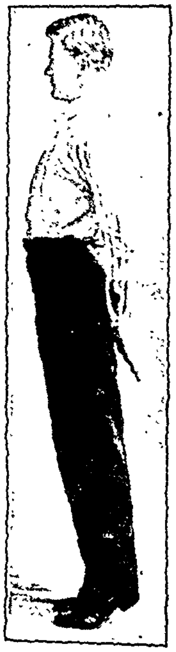

Fig. 13 (sixth exercise).—Arms meeting behind the back.

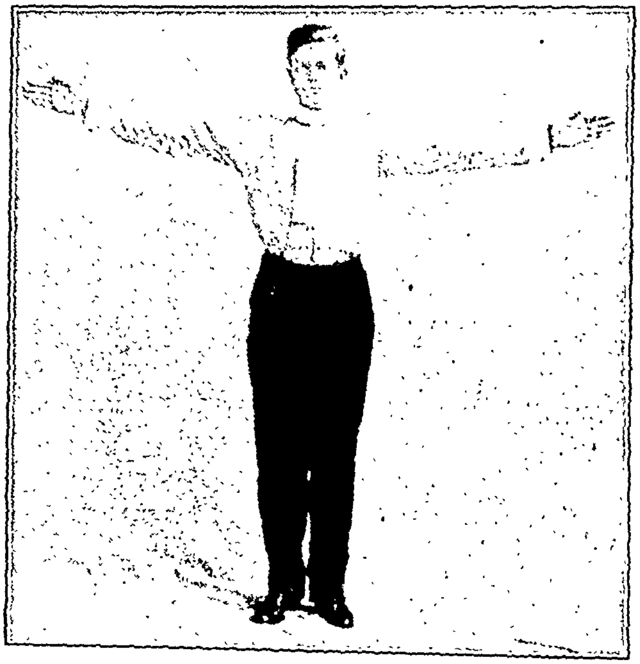

Fig. 14 (sixth exercise).—Arms again forward.

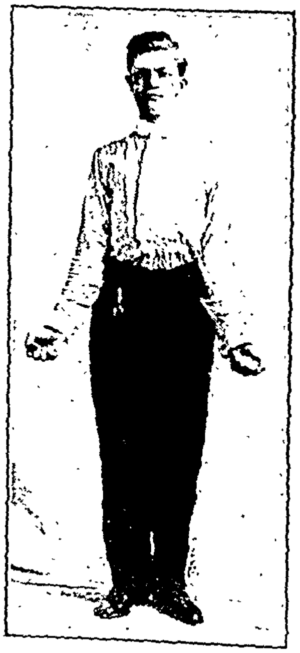

Fig. 15 (additional exercise). —Expiratory effort, arms outward.

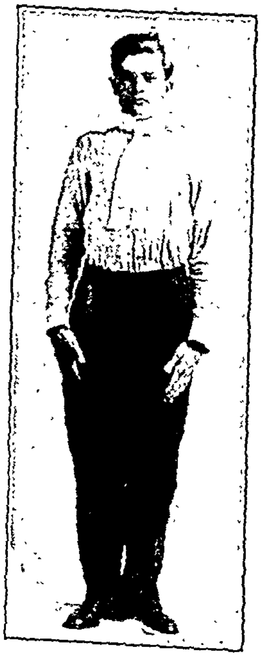

Fig. 16 (additional exercise). —Inhalation.

A draftsman, bookkeeper, clerk, tailor or shoemaker will rarely make a good farmer; but if the precautions just mentioned are taken, these men will do better and be happier when they can return to their former occupations. Of course there will be exceptions, and if the soldier's occupation in civil life was one in which he had been exposed to the inhalation of a great deal of dust or irritating gases, or to the extremes of cold and heat, night work or unusual physical strain, it will be wiser to choose another way for him to earn a living. Lastly, all soldiers and sailors discharged as arrested cases, whether or not they have had postsanatorium treatment, should be impressed with the necessity of having the chest examined at least every three months for the first year or two, and later on semiannually, so as to guard against any insidious recurrence of the trouble. Any intercurrent indisposition or actual disease of whatever kind should be considered important enough to have medical advice sought immediately. The recovered tuberculous soldier or sailor should be particularly careful in times of influenza and pneumonia epidemics, such as we are undergoing at present. He should avoid overcrowded assemblies, keep his bowels in good condition, and above all guard against overfatigue. Let him abide by the simple rule never to continue to work physically or mentally when already tired from manual or brain labor and never to work to the extent of getting overtired (acutely fatigued). It is my conviction that the fatigue poisons are as much responsible for the prevalence of infectious respiratory diseases as careless sneezing and coughing. Whether the periodic examination of the discharged one-time tuberculous soldier shall be done by the surgeon of the nearest military post, by a civilian practitioner, by a physician especially qualified and appointed by the government, or by the medical staff attached to the various tuberculosis institutions or under the direction of the National Tuberculosis Association, is a matter which should be worked out carefully by the respective authorities.

I am convinced that by carrying out systematically the methods I have described, to prevent relapses in arrested cases of tuberculosis, and by the subsequent periodic reexamination of the one time tuberculous soldier or sailor, not only will many valuable lives be saved, so greatly needed in this period of reconstruction, but individuals and families will be spared a great deal of suffering, and thousands of dollars of pension money will be saved to our government.

16 West Ninety-Fifth Street.

MASTOIDECTOMIES UNDER LOCAL ANESTHESIA

A BRIEF REPORT ON NINE MASTOIDECTOMIES (ONE DOUBLE), UNDER LOCAL ANESTHESIA AT THE BASE HOSPITAL, CAMP UPTON, N. Y.

C. T. PORTER, M.D. (Boston)
Captain, M. C., U. S. Army; Chief of the Otolaryngologic Department
CAMP UPTON, YAPHANK, L. I., N. Y.

During the measles and pneumonia epidemic of the winter of 1917-1918, it was found necessary to operate in several cases in which acute mastoiditis complicated the pneumonia. In the absence of an expert in nitrous oxid and oxygen anesthesia, and part of the time of one in nitrous oxid anesthesia, it was deemed expedient to perform these operations under a local anesthetic. There was also one case from the recent influenza epidemic in which the operation was started under nitrous oxid-ether anesthesia; unpleasant symptoms arose when the anesthetics were switched, and it was decided to give the patient local anesthesia.

The method of administration was as follows: The patient was first given one-fourth grain of morphin subcutaneously, and in half an hour a 0.5 per cent. solution of cocain or procain, when the latter became available, was injected into the skin along the line of incision. The injection was then carried into the deeper layers and finally under the periosteum over the entire area of the mastoid. The insertion of the sternomastoid muscle and the posterior canal wall were injected at the last. About 15 c.c. of a 0.5 per cent. solution were used, in each case, although as high as 30 c.c. of a procain solution were used in one case—a double mastoiditis—and as low as 6 c.c. of a 0.5 per cent. solution of cocain were used in another case.

After waiting for from five to ten minutes, the operation was started and carried on in the usual manner. The patient usually complained somewhat of the pounding necessary to remove the cortex, but all admitted afterward that there was little actual pain.

In only one case did I find it necessary to resort to general anesthesia. In this case, that of a Russian who was very nervous and apprehensive from the start, we finished under chloroform.

One case in which I did a double mastoidectomy at the same time deserves special mention, as the patient was so ill at the time that it was not deemed advisable to give any type of general anesthetic.

The most remarkable thing about these cases, in my opinion, was the almost total absence of any shock following the operation. This indicates more conclusively than the statements made by the patients that there was very little pain or none at all. This was also observed by Major Harlow Brooks, then chief of the medical service.

In this series of cases the incidence of dry middle ears was 100 per cent., and there was no mortality. A patient with double mastoiditis, the most seriously ill of all, is now recovered and ready for discharge. He has been in the general surgical service for a recurrent empyema and multiple abscesses. Although ten days after the operation for mastoiditis a blood culture revealed *Streptococcus hemolyticus*, it was decided that the blood stream infection probably came from the chest condition, rather than from an infected sinus thrombosis, as neither sinus was exposed at the time of operation, and the overlying bone was found healthy.

REPORT OF CASES

Case 1.—D. J., a colored man, aged 21, farmer, admitted to my service, Jan. 3, 1918, for epistaxis, had had repeated nosebleeds for several years, and had suffered from swelling of the feet, legs and abdomen for two years. Urinalysis revealed albumin, + + +, and granular, waxy and epithelial casts. The specific gravity of the urine was 1.007. An additional diagnosis of chronic parenchymatous nephritis, with cardiac hypertrophy, was made.

January 6, the patient developed acute, bilateral, purulent otitis media.

January 7, 50 c.c. of horse serum were given to control a nasal hemorrhage. The nose had been packed repeatedly. The right ear cleared up after free paracentesis. The left ear continued to discharge.

February 14, there was a slight swelling over the left tip.

February 15, a simple mastoidectomy with the usual incision was performed. The sinus and dura were exposed. The entire tip was removed. An iodoform wick was inserted into the neck in addition to the regular mastoid packing. No pus was found in the neck. One-fourth grain of morphin, and 10 c.c. of a 0.25 per cent. cocain solution were used.

April 29, the patient was discharged from service. The ear was dry and the wound healed.

Case 2.—S. V., white man, aged 22, admitted to the hospital, Jan. 20, 1918, for measles and bronchitis, later developed pneumonia.

June 26, he complained of ear ache.

June 27, the left drum ruptured. I saw the patient after the rupture. He had considerable bronchial irritation, and it was thought unwise to give ether. The urine showed a trace of albumin. The specific gravity was 1.025. Culture revealed *Staphylococcus aureus.*

July 1, A simple mastoidectomy was performed. Fifteen c.c. of a 0.5 per cent. solution were used.

August 17, the patient was discharged, with the wound healed and the ear dry.

Case 3.—R. J., white man, aged 23, farmer, admitted to the hospital, April 27, 1918, for measles, developed bilateral bronchopneumonia, April 30; mumps on the left side, May 4; pharyngitis and acute follicular tonsillitis, May 5. May 6 he showed signs of acute arthritis in all joints. May 7 there were signs of pericarditis with endocarditis. May 11 he developed acute purulent otitis media on the left side, for which free paracentesis was employed, and May 12 on the right, with the same treatment. There were positive signs of mastoiditis on the left side, May 24, and on the right side, May 26. Pus from the ear showed *Staphylococcus aureus,* May 25.

The urine was negative. Blood culture, June 10, revealed *Streptococcus hemolyticus.*

May 31, a simple double mastoidectomy was performed. One-half grain of morphin and 30 c.c. of 0.5 per cent. procain were used.

June 29, an abscess developed on the left scapular region of the back; also somewhat later on the legs. There was empyema on the left side. A specimen of pus from these showed streptococci.

August 15, the wound was healed and the ears were dry.

November 12, the patient still had abscesses on the body.

November 20, the patient was ready for discharge from the hospital, cured.

Case 4.—B. A., white man, aged 25, admitted to the hospital with measles, developed pneumonia and later an acute infection of the left ear. Paracentesis was done. The pus from the ear showed *Streptococcus hemolyticus*.

April 26, a simple mastoidectomy was performed. One-fourth grain of morphin and 6 c.c. of 0.5 per cent. cocain solution were used. The wound was left open, the better to drain what was diagnosed as the beginning of a temporal abscess. In this case also an improvised drainage tube was used in connection with neutral solution of chlorinated soda. The result of this was negative so far as any difference could be made out. Later the edges were freshened and the wound was sutured. July 18, mumps developed.

August 14, the patient was discharged from the hospital. The wound was healed and the ear dry.

Case 5.—S. W., white man, aged 25, farmer, admitted to the hospital with measles, several days later developed bronchopneumonia. He had acute otitis media on the right side. Paracentesis was done with free drainage.

May 6, a simple mastoidectomy was performed. One-fourth grain of morphin and 15 c.c. of 0.5 per cent. cocain solution were used.

June 26, there was a second attack of bronchopneumonia, from which the patient died two weeks later. At the time of his transfer to the medical service, his ear was dry but the wound was not entirely healed.

Case 6.—T. S., white man, aged 25, admitted to the hospital with measles, later developed bronchopneumonia. Paracentesis was done for acute, purulent, right otitis media.

June 5, a simple right mastoidectomy was performed. One-fourth grain of morphin and 30 c.c. of 0.5 per cent. procain solution were used.

July 16, the patient was discharged from the hospital. The wound was healed and the ears were dry.

Case 7.—D. J., white man, aged 27, admitted with measles, later developed bronchopneumonia. Paracentesis was done.

June 4, a simple right mastoidectomy was performed. Procain solution, 0.5 per cent., and chloroform, 90 gm., were used. The patient was too nervous for local anesthesia.

July 10, he was discharged from the hospital with the wound healed and the ear dry.

Case 8.—H. W., white man, aged 22, farmer, admitted to the hospital, Oct. 18, 1918, with influenza and bilateral bronchopneumonia, had pain in the left ear, November 1, and some mastoid tip tenderness, with free discharge, November 4.

November 19, a diagnosis of acute left mastoiditis, with Bezold's abscess, was made. The patient was immediately transferred to the ear service.

November 20, a simple left mastoidectomy was performed. The tip was necrosed. The neck was drained. Pus was found in the soft tissues, just *outside* the tip. One-half grain of morphin and 8 c.c. of 0.5 per cent. procain solution were used. Pus from the tissues showed *Staphylococcus aureus.* The patient felt little if any pain during the operation and kept up a conversation with the nurse the whole time. There was absolutely *no shock* following the operation. The patient was up and around the ward the next day.

November 27, the middle ear was dry. The wound healed by first intention.

CAMPTOCORMIA (BENT BACK)

GEORGE W. HALL, M.D.
CHICAGO

The term "camptocormia" was originally used by Souques,[1] who presented a case before the Société de neurologie in Paris in February, 1915, as applied to the forward flexion of the body with or without lateral inclination. Hurst[2] has reported similar cases under the name "bent back." The particulars of sixteen cases of camptocormia have been presented by Rosanoff-Saloff,[3] from whose article some of the accompanying illustrations are taken. It is stated that the most careful examination of these patients has revealed no organic lesions. The author divides the patients into two classes, namely, those who had been wounded, and second, those showing no evidence of wounds. The first class included only two of the sixteen cases,

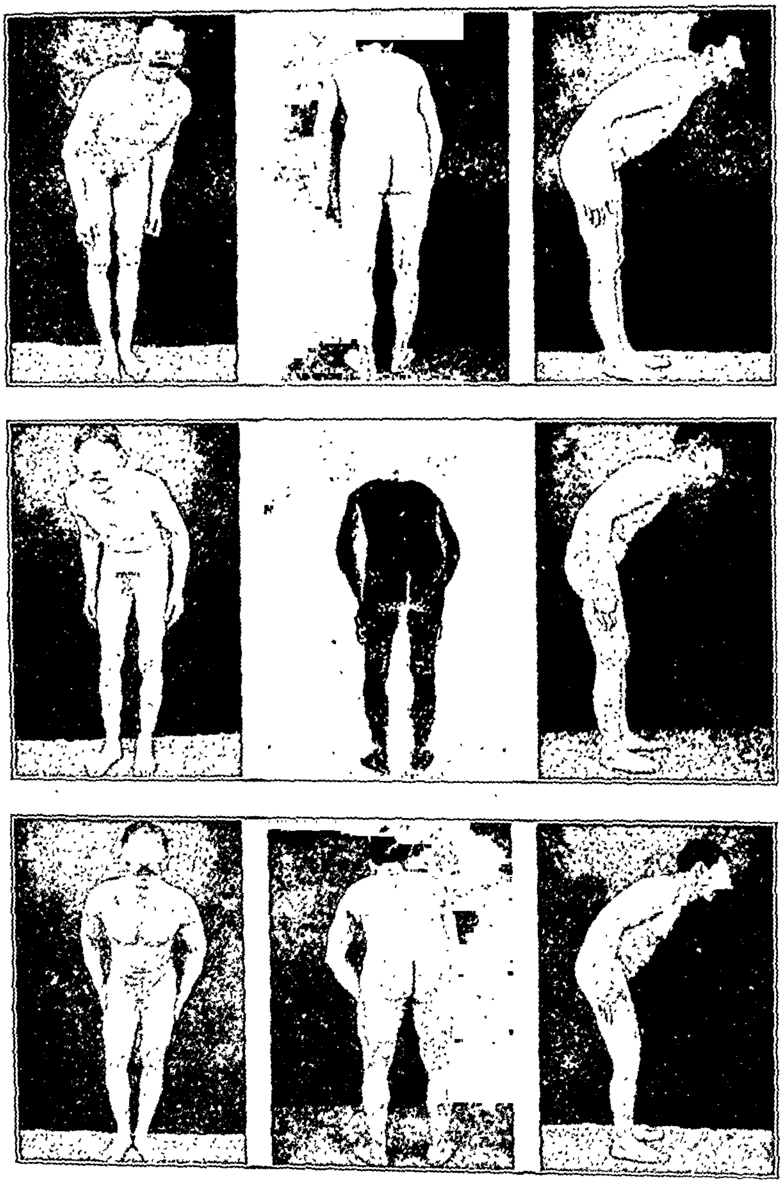

Fig. 1.—Several camptocormic soldiers examined and followed by Rosanoff-Saloff for several months at the hospice Paul Brousse (*de Villejuif*) in the service of Souques. All three present pure camptocormia.

and the injury was distant from the part of the body bent. In the second class the men had been the victims of shell explosion and had been thrown to the ground by the force of the explosion and suffered some dorsolumbar traumatism. In all the cases lumbar pain was the important symptom. This gradually subsided after many days in bed, and on getting up the patients found they could not stand erect even though all pain had disappeared. Hurst states that the posture adopted to relieve the pain is regarded by the patient to be directly due to the injury as well as the pain.

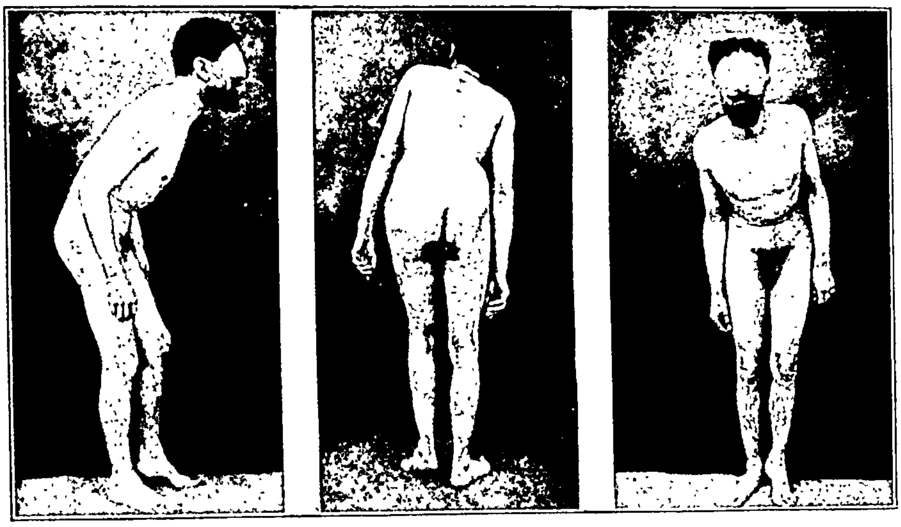

Fig. 2.—Camptocormia combined with lateral inclination.

REPORT OF CASE

The subjoined case conforms to the class which these authors have described:

J. S., aged 30, an enlisted soldier, Oct. 29, 1917, received an injury to the lower part of the abdomen on the left side and a bruise to the left arm, by a box weighing 115 pounds falling across his abdomen from the lowest step of a stairway. He was not seriously disabled at the time, but about twelve days later his body became somewhat flexed toward the left when sitting, standing or walking. The condition was looked on by the surgeons in charge as purely functional in character, and on Nov. 22, 1917, it was decided to operate on a varicocele, hoping to improve the former ailment. Immediately following this operation the patient's symptoms became aggravated in that he complained of increased pain and a severe "drawing" sensation of the left testicle on his attempting to asume an erect position of the body, and he was of the opinion that both testicles had become atrophied as the result of the operation. The trunk at the same time became considerably more bent toward the left. He was given a furlough, and his wife gave out the report that he had become impotent. This report caused expressions of sympathy among female organizations, which developed an active interest in the cause and gave the case rather widespread publicity.

In the meantime the patient's body became still more flexed toward the left. In June, 1918, Dr. Peter Bassoe and I were requested to examine the patient and render a report to the government, as we were serving in the capacity of contract surgeons at the time. Our examination revealed no organic changes in the central nervous system. Roentgenographic reports were negative. The patient showed diminished tactile and pain sense on the left side of the body. There was no hemianopsia, and the deep reflexes were but slightly increased. The Babinski sign was absent. At the time of our examination, the patient's body was greatly flexed toward the left while he was sitting or standing, and when he walked his left hand would rest on his left leg near the knee. He complained of severe "drawing" sensations in the testicles, extending toward the lumbar region on the left side. The diagnosis of a purely functional disturbance was made, and it was recommended that he be sent as far away from home as possible and be placed in a neuropsychiatric hospital.

PATHOGENESIS

In seeking the pathogenesis, Rosanoff-Saloff found that all of these sixteen patients were more or less neuropathic. Four of the patients gave a decided neuropathic family history, such as alcohol and epilepsy.

Sicard[4] examined the spinal fluid in fifteen cases within from ten to fifteen hours after the shock or injury and found the presence of hyperalbuminosis, with no other findings pointing to organic changes in the central nervous system. Souques likewise found hyperalbuminosis in three cases.

DIAGNOSIS AND TREATMENT

This condition resembles no disease except spondylitis deformans. While in the majority of cases uncomplicated kyphosis is present, Hurst has seen lordosis, lateral curvature and combined lateral curvature and kyphosis. He reports several cases in this connection.

Hurst states that unfortunately the medical officer too often makes the mistake of prescribing a treatment which causes the patient to believe that he is the victim of a very serious ailment. Hurst believes it is a purely functional disease and that psychotherapy is the treatment, electricity being used as only one of the means of suggestion. The application of a plaster jacket after straightening the spine under anesthesia will do no good and may do harm by more firmly fixing the idea in the patient's mind. He believes that hypnotism may be useful but that simpler methods, such as persuasion and reeducation, are better. The patient should be told that it is a bad habit, and he recommends strict discipline in effecting a cure. An illustration of his method of treatment is reproduced in Figure 5, showing how the patient is straightened out on the board in a horizontal position with his feet firmly fixed against the footboard placed at right angles. He is then gradually raised to the erect position, and in that way the author impresses the patient that his

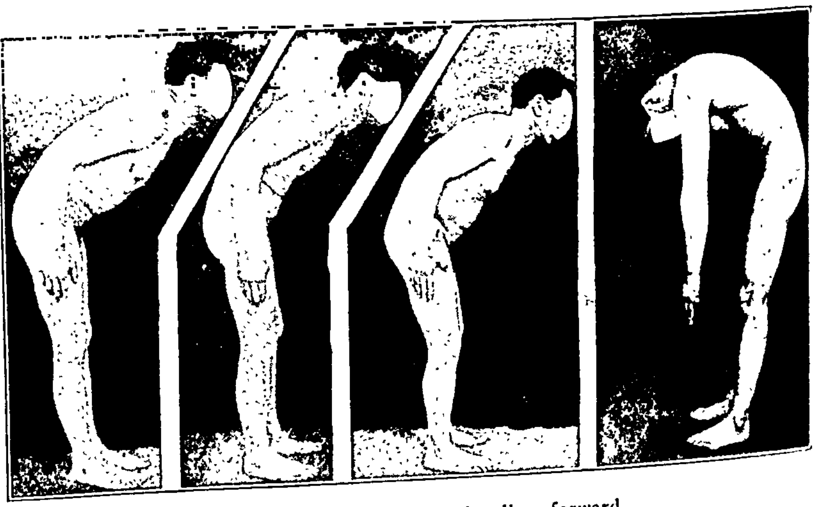

Fig. 3.—Normal man bending forward.

---

[4] Sicard, J. A.: Bull. et mém. Soc. méd. d. hôp. de Paris 30:5[illegible] 1915,

body can be kept in an erect position and thus effects a cure.

Souques says that pure camptocormia is easily cured by persuasive electrotherapy. In a normal person, according to Rosanoff-Saloff, a long continued muscular immobility tends to produce the fixed attitude, but the patient's will power readily corrects the trouble; whereas, in a neuropath, the position is accepted by a sort of inertia or autosuggestion, and he adapts himself to it. Consequently, the prognosis in such cases is not good.

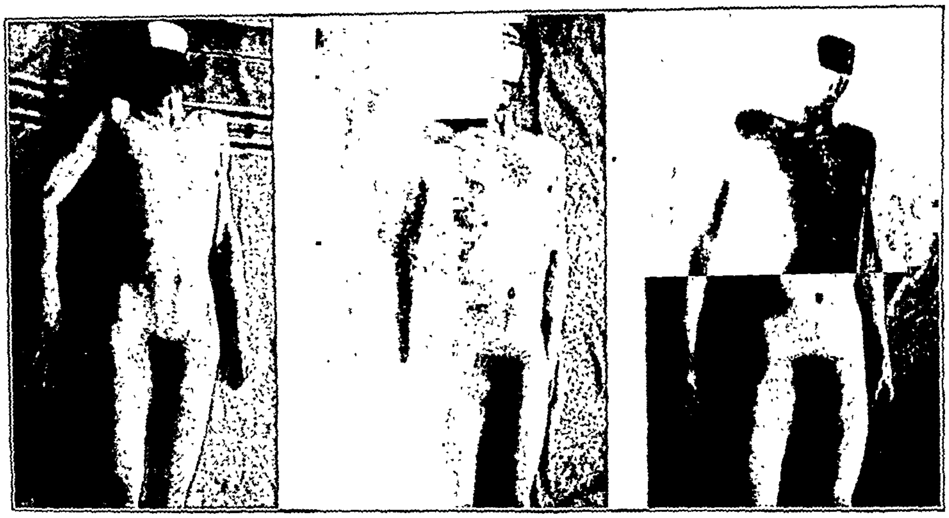

Fig. 4.—Among some subjects, the effort of straightening produces a classic trembling of the lower limbs which persists for from fifteen to twenty minutes. On the other hand, on a horizontal surface, straightening is complete and spontaneous in the case of most persons who are ill.

Rosanoff-Saloff further states that if the flexed position is corrected, the patient is prone to fall back into the former condition on the slightest provocation, and that hospitalization confirms him in his mental attitude.

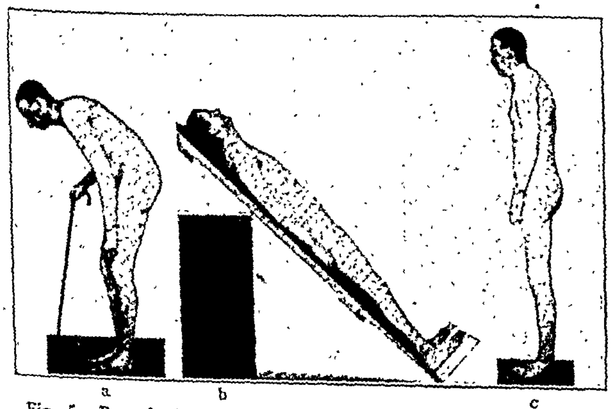

Fig. 5.—Bent back of five months' duration: *a*, before treatment; *b*, under treatment with "back-board"; *c*, after treatment.

These patients should be treated in a neuropsychiatric hospital and under the strictest discipline.

104 South Michigan Avenue.

Changing His Brand for a New Start.—Sir James Crichton-Browne relates the story of the provost of a Scottish town who had presided at a teetotal meeting. The provost wound up the meeting by a few remarks in which he said: "I confess I am not a total abstainer; I take a little whisky and water daily, but I may say that after the speeches I have heard this evening, had I to begin life again I would start on milk."

ANTALGIC SPINAL DISTORTION

JOHN SALIBA, B.A., M.D., C.M.
Surgeon, Elizabeth City Hospital
ELIZABETH CITY, N. C.

By antalgic spinal distortion I mean that peculiar condition characterized by an unnatural direction of the back, without any marked organic change in its structures, and adopted originally in order to relieve pain.

Some physicians serving in the war have observed among sick and wounded soldiers and sailors certain patients sitting, standing or walking in a stooping attitude, with round shoulders and back, or in an attitude wherein the back has assumed abnormal direction varying from moderate asymmetry to extreme distortion. Attention has for some time been directed to this condition, and an extensive literature on the subject has grown in France; but its true nature has rarely been recognized.

French writers have given this condition many denominations, such as plicature vertébrale, camptocornie (Souques and Rosanoff-Saloff[1]), spondylose antalgique (Sicard[2]), and campto-rachis (Laignel-Lavastine and Courbon[3]).

So far as my reading has extended, I find no mention of it in the medical literature of this country; and in that of England I find only one paper, under the title of "The Bent Back of Soldiers."[4]

Although this condition has of late been observed largely in men in the service, it would be incorrect to limit it to them, for many surgeons have undoubtedly seen patients in civil life who, after an abdominal operation, say an appendectomy, or after an attack of lumbago or an accident, developed a stooping attitude, bending forward with rounded shoulders and back, and walking slowly and trembling.

ETIOLOGY

The affection has been encountered especially in people who have a predisposition to the varied and ill-defined morbid conditions which may be provoked in most of the systems, and which are included under the name of hysteria and neurasthenia. At present it is difficult to say in what proportion it affects men and women in civil life. Military or naval service plays a great part as a provoking agent, where men are subjected to prolonged watching, physical overwork and emotions, and are disposed to malinger.

The main factor in developing the condition is pain, which may be due to a pathologic process or may be psychic. Its location need not be limited to the back, or to any particular organ or structure, for it may be

4. Hurst, A. F.: Brit. M. J. **2**: 621 (Dec. 7) 1918.

in the abdomen, thorax or other regions. Most commonly, however, it follows backache, and the causes of backache are too many and too vaguely enumerable to be mentioned here. Among the various causes of pain leading to such an affection I may mention an accident, a blow, a wound, or a fall on or about the back or abdomen, a diseased organ, as an appendicitis, the after-effect of an operation or a lumbar puncture, an attack of rheumatism or lumbago, and exposure to cold and damp.

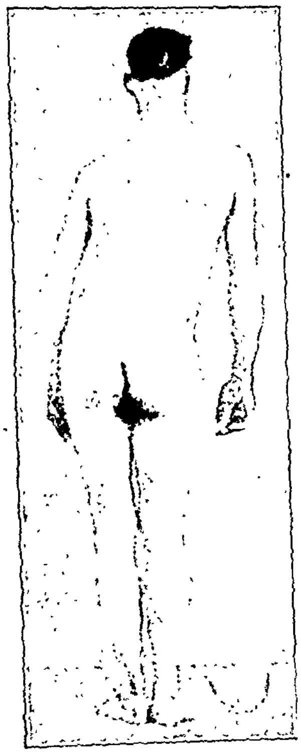

Fig. 1.—Patient before treatment.

PATHOLOGIC ANATOMY

The unnatural direction of the back is due to no pathologic changes in its structures, but is adopted in order to relieve the pain. This pain in some cases may become continuous, and is due chiefly to the constant stretching of the ligaments and small muscles of the spine. The diversity of the conditions that have caused the pain may lead us to confusion. A bruising, following an injury, may cause fibrositis, myositis or both—a pathologic process. Rheumatism or lumbago also produces pathologic changes in the fibrous and muscular tissues. In patients with a history of such conditions and a faulty position of the spine, bruising soon disappears. The rheumatism or lumbago eventually improves. The pain is either completely relieved or is less severe than it was at the onset, and yet the posture adopted remains. The more or less permanent organic element, if any, left from the effect of the bruise or the rheumatism is not in itself all sufficient to justify the patient in assuming such a posture. A psychic element is entirely or chiefly responsible for it. Roentgenoscopy in these cases reveals no organic lesion of the spine.

DIAGNOSIS

The distortion arises from the pain and not the pain from the distortion. The appearance of the patient, and the absence of true organic lesion, after roentgen investigation, are distinctive signs and symptoms to make the diagnosis an easy matter. Cases of various kinds of deformities, as kyphosis, lordosis and scoliosis, mild or severe in degree, uncomplicated or combined, have been seen which owe their origin to this affection. In some cases antalgic kyphosis may be difficult to differentiate from spondylitis deformans. A careful observation of the progress of the disease can settle the diagnosis. Further, in spondylitis deformans, a change of position does not affect the spinal curve and its rigidity. In antalgic kyphosis, lying with the back on the table invariably permits of reposition of the spinal curve partially or totally.

TREATMENT

We have seen that although the etiology of this condition is variable, its pathology is always psychic, and has generally, if not entirely, no organic element. We are therefore justified in considering the phenomena of this condition the result of autosuggestion, and they can be reproduced by the will. In ordering a treatment, we must keep in mind that these phenomena will disappear in the same way that they are reproduced, under the exclusive influence of persuasion. Psychotherapy should replace the various and elaborate methods of treatment, and remove the impression from the patient's mind that he is suffering from some serious disease. The patient believes that his abnormal posture is the cause of his pain, instead of the opposite, and the medical man, by prescribing treatment with drugs, massage, counterirritants, electricity, the plaster-of-Paris jacket, etc., reinforces the autosuggestion of the patient by heterosuggestion. From the failure of such treatment, the patient is led to believe that his condition is incurable.

The subjoined case, under my care recently, shows that some cases of abnormal curvature of the spine, which have proved very resistant to various forms of treatment, and consequently considered incurable, are really examples of antalgic spinal distortion.

REPORT OF CASE

Lateral curvature of the spine, of three months' duration, cured by psychotherapy in one week.

Seaman A. R. H. of New Hampshire, aged 27, with nearly two years' service in the U. S. Navy, was admitted to the Elizabeth City Hospital suffering from lateral curvature of the spine.

At the time of his enlistment, early in 1917, his height was 71 inches, weight 150 pounds, circumference of chest 34 inches, expansion 4 inches, vision and hearing normal. About Oct. 1, 1918, while he was on night duty on board a submarine chaser at Baltimore Nets, his back began to pain him. The pain started at the end of the spine and extended upward to the neck. At the end of the watch, his body was drawn over to one side, and he was unable to hold himself straight. The pain and the faulty position continued. He remained on board ship until October 25, when he was sent to the U. S. Naval Hospital, Norfolk, Va. While there he was treated with hydrotherapy, massage and a plaster-of-Paris jacket. Several roentgen examinations were made, and detected no organic spinal lesion.

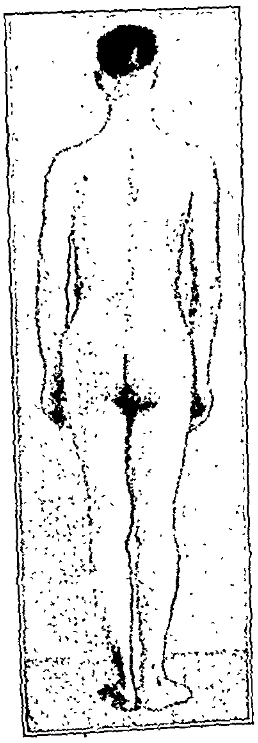

Fig. 2.—Patient after treatment.

December 28, he was transferred to my care, at the Elizabeth City Hospital, for further treatment. On admission, the patient stated that his back ached continuously. There was a lateral curvature of the spine to the left in the lumbar region and to the right in the dorsal region, with corresponding prominence of the left hip and right shoulder. The faulty position could be corrected by manipulation while standing.

An explanation of the condition was given the patient. He was told that there was nothing serious the matter with his spine, and that the backache would soon disappear if he would relax his muscles and stand straight. First he was made to stand erect with his back to the wall, and then to walk forward in the same position. Similar simple methods of persuasion and reeducation continued for one week, and the patient recovered completely.

Health and National Efficiency.—Care for the health of the people is the secret of national efficiency. It is the secret of national recuperation.—Lloyd George, Manchester Speech.

THE VALUE OF THE WASSERMANN REACTION IN PREGNANCY

EDWARD L. CORNELL, S.B., M.D.
Attending Obstetrician, Chicago Lying-In Hospital
AND
A. W. STILLIANS, M.D.
Consulting Dermatologist, Chicago Lying-In Hospital
CHICAGO

The report made by Falls and Moore[1] of a positive Wassermann test in 11.3 per cent. of 160 cases of pregnancy raised a doubt in the mind of one of us (E. L. C.) as to the correctness of these figures, at least in private practice. If they are correct, a very large number of syphilitics in private obstetric practice are escaping detection altogether. In support of this doubt, the figures obtained in other series showed a considerable variation. Commiskey[2] reported 8 per cent. of positive results and Menten[3] 13.45 per cent. positive, while Adair[4] obtained only 6.5 per cent. positive.

We feel justified in suspecting that the high proportion of syphilitics in these series and the variation in results were due to the presence in them of charity patients, and especially negroes. We therefore decided to test the question by a parallel series of cases, one among private patients and another among those entering the Chicago Lying-In Hospital for free care.

The cases in the first series were consecutive, every patient in the practice of one of us (E. L. C.) being given a Wassermann test at her first visit. Some appeared early in pregnancy, while others were not seen until the time of delivery. A few were consultation cases.

In 107 cases, four gave distinctly positive reactions. Two with doubtful reactions have been excluded from consideration, as every other indication of syphilis was lacking, and they have healthy children over a year old. There were, therefore, 3.6 per cent. positive reactions; two of the four gave a history pointing to syphilis, while the other two gave no history at all suggestive.

Case 1.—Mrs. J. contracted syphilis from her first husband, her first pregnancy resulting in a miscarriage at the sixth month. The second pregnancy resulted in a stillbirth at term, and the third (by the second husband) in an apparently healthy child. Previous to and during this pregnancy she received intensive treatment. The child is apparently healthy at the age of 2. She has recently been delivered of a child which shows at the age of 4 months signs of syphilis. Treatment was neglected until near the end of pregnancy.

Case 2.—Mrs. P. gave a history suggestive of syphilis. Her first pregnancy resulted in an abortion, the second in a small child which lived only a few hours. The third terminated in craniotomy because of a large child in the presence of a contracted pelvis. At the third month of the fourth pregnancy, the diagnosis of syphilis was made clinically and serologically, active treatment was instituted, and a live child weighing 9½ pounds delivered by cesarean section after a labor test of twenty hours. The child is apparently healthy without antisyphilitic treatment.

Case 3.—Mrs. C., primipara, gave a history negative for syphilis. She refused treatment and was delivered elsewhere. No information has been obtainable as to the result of her pregnancy.

Case 4.—Mrs. B. was delivered of a full term macerated fetus in her first pregnancy. The second resulted in an abortion. She gave no history suggestive of syphilis.

In reviewing these cases one is struck by the large number in which there is a history of abortion or stillbirth. In all probability these are not syphilitic. Twenty-one of the 103 cases gave such a history, a percentage of 20.3 +. It certainly does not seem reasonable to ascribe any large proportion of these accidents to a syphilis which has since become extinct, or is beyond the reach of clinical or serologic recognition. DeLee's observation that other infections than syphilis cause stillbirths has stimulated us (E. L. C.) to seek the cause of the accidents in focal infection.

Twenty-one cases, presented in the accompanying table, aside from the syphilitic, have a history of an abortion or stillbirth. This is a percentage of 19.6.

Our second series corresponds to that of Falls and Moore, except that there were no negro patients. It included 101 charity patients entering the Chicago Lying-In Hospital. Most of them were delivered in the hospital, but some left before delivery. Ten gave positive Wassermann reactions, a little less than 10 per cent. Of these two had active skin lesions and two gave a history pointing to syphilis. One gave a history of repeated miscarriages, and one had cardiovascular disease, from which a suspicion of syphilis might reasonably arise. The other four gave no history or sign of the disease, and would no doubt have escaped diagnosis except for the serum test. The fact that the percentage of syphilitics in the second series was so much higher than in the first corresponds with the higher proportion of syphilitics among charity patients. About a third of the women in this series acknowledged being unmarried, while 40 per cent. of those with positive serum tests were unmarried. Half of the syphilitic patients were in their first pregnancy.

ABORTIONS OR STILLBIRTHS IN TWENTY-THREE CASES ASIDE FROM THE SYPHILITIC

	Parity	Live Children	Abortions or Stillbirths	Remarks
N. S.	7	1	6	Last case a double placenta at 6 mos.
R. M.	5	1	4	Bad teeth
E. B.	2	1	1	Full [illegible]
C. E.	4	1	3	T[illegible]
A. L.	3	1	2	Sc[illegible] died; status
R.	3	1	2	One craniotomy; one miscarriage
K.	3	2	1	Seven months premature
M.	2	0	2	First eclampsia, second abortion
H.	3	0	3	All below 4 months
T.	2	1	1	
K.	9	2	7	
G.	3	2	1	Retained placenta first and second abortion
B.	1	0	1	4½ months; 10 abscessed teeth
C.	4	1	3	First criminal, second and third accidental
M.	2	1	1	Stillbirth
E.	3	2	1	First, three months
S.	3	1	2	
O.	3	2	1	Angular pregnancy
S.	2	0	2	
P.	4	1	3	First, O.K.; second, stillbirth; third and fourth, died in utero at six months; delivered at term
McE.	2	1	1	Vaginal infection
	70	22	48	

The technic of our tests corresponds with the original Wassermann technic except in generally accepted changes, such as the use of multiple alcoholic extracts as antigens, and the titration of complement and fixation at room temperature for half an hour and then in the water bath at 37 C. for half an hour. In addition, the complement was titrated for its fixation power in the syphilitic system, and the strength of reaction controlled by a titration of a mixture of glycerinized positive serums.[5]

[3] Menten, M. L.: Am. J. Obst. 78:514 (Oct.) 1918.
[4] Adair, F. L.: Am. Jour. Obst. 78:678 (Nov.) 1918.

We had no false positives in eclamptics, as reported by Falls and Moore, but had several weak positive or doubtful reactions in cases which we finally concluded were nonsyphilitic. These seem to be more common in the pregnant than in the nonpregnant, but did not run parallel with toxicity, for they were observed in a number of healthy women with negative urinary findings, while they were absent in others distressingly toxic. They occurred much oftener with the heart antigens than with the syphilitic liver antigens.

The phenomenon reported by Menten, who observed positive reactions before parturition change to negatime immediately after childbirth, has been observed by one of us (A. W. S.) in a woman whose positive reaction did not yield to treatment as intensive as was thought safe throughout pregnancy. Within a few days after delivery a frank negative was obtained, which again became positive in a few months in spite of treatment. The child is clinically and serologically negative at the age of 8 months.

The glycerinized positive control was checked in its work of protecting against too finely drawn tests by the use of 0.4 c.c. of serum, twice the maximum dose, as serum control. Anticomplementary action is very quickly shown by such a control, while, on the other hand, the danger of native amboceptor in such a quantity of serum was guarded against by testing each serum for amboceptor. The full dose of serum, 0.2 c.c., was combined with the full dose of blood suspension and one hemolytic titer of complement. If hemolysis resulted, the presence of at least 2.5 titers of native amboceptor was demonstrated, and no rabbit amboceptor was added to the tubes containing this serum. Since our serums have been inactivated for half an hour in the water-bath at 54 C., we have seen very few serums with this amount of native amboceptor.

In spite of the phenomenon of Menten, it is probable that the well known tendency toward latency of syphilis in women tends to produce a negative Wassermann reaction in a larger percentage of cases than in men, and we therefore feel certain that some syphilitics in both our groups escaped detection. Examination of the cord and placenta or of the dead infant will supplement the serum test in these cases. Accepting even our small percentage of positive results in the private cases for the general prevalence of syphilis among women, the estimate given by Pusey[6] would be swollen from 1,200,000 to 4,320,000 adult syphilitics in the United States. When the many women in the charity class and their high percentage of syphilitics are considered, an appalling figure is reached. The crying need for activity against this "third great plague," as it is called by Stokes, is today apparent to all. As an important stronghold of the enemy, we would emphasize the pregnant woman. If syphilis is diagnosed early, the lives of many children may be saved from destruction or deformity worse than death, and thousands of families every year preserved from the greatest torture of mind, as well as from bodily ills. Even though only 3 per cent. of the pregnant were found syphilitic, and only a third of these would escape detection by clinical means, the trouble and expense of the routine Wassermann tests in the pregnant are fully justified.

SUMMARY

1. Our first series of private cases of pregnancy gave only 3.6 per cent. of positive Wassermann reactions.
2. Our second series of charity cases gave nearly 10 per cent. of positive reactions.
3. More than one third of these positive cases were detectable only by the serum examination.
4. Routine Wassermann reactions in pregnancy are amply justified by these findings.
5. A surprisingly large number of apparently nonsyphilitic women give a history of frequent abortions.
6. The Wassermann reaction should be checked by searching for the spirochete and by postmortem examinations when possible.

A NEW TREATMENT FOR THE MORPHIN HABIT

C. S. BLUEMEL, M.A., M.D.

DENVER

It is common knowledge that a person addicted to the use of morphin may gradually increase the dose of the drug without suffering toxic effects, so that in a few months he may take with impunity a dose that originally would have been fatal. In other words, he establishes an immunity to the drug; and it seems probable that the immunity is due to the presence of an antibody or antitoxin in the blood.

When later the morphin is withdrawn, the antibody remains in the blood unneutralized, and according to the theory that is generally accepted, it is this antibody that gives rise to the characteristic symptoms of nervousness, leg pains, sweating, nausea, vomiting, diarrhea, etc. These symptoms are relieved when morphin is administered, and the amount required to give relief is precisely the dose to which the morphinist has habituated himself. A less amount relieves the symptoms only in part, while an amount in excess of it gives again the toxic symptoms of morphin. Thus a morphinist can estimate pretty accurately an unknown dose that has been given to him by a physician; and the physician, by observing the alleviation of the patient's symptoms, can titrate in a sense the patient's antibody much as he titrates complement in vitro.
